

Lead in the Ohio River Basin
The Ohio River Watershed Pollutant Reduction Program

The Ohio River Valley Water Sanitation Commission

November 1998

INTRODUCTION

This report is prepared as part of the Ohio River Watershed Pollutant Reduction Program (ORWPRP) being conducted by the Ohio River Valley Water Sanitation Commission (ORSANCO) with funding assistance from the U.S. EPA and support from the Commission's member states. The goal of ORWPRP is to generate necessary information to evaluate the need for and achieve meaningful reductions of pollutants inhibiting the beneficial uses of the Ohio River and its tributaries. The purpose of this report is to present available information on lead pertaining to water pollution within the Ohio River Basin. Specifically, data is included on the geographic extent and severity of lead contamination in various aquatic media along with potential sources of such contamination.

Lead is a naturally occurring metal that is found in small amounts within the earth's crust. Commonly, lead is used in the production of ammunition, batteries, metal products, pipes, and in a large variety of medical, scientific, and military equipment. While the element exists naturally, human activities have spread lead and substances that contain lead to all parts of the environment. Lead is found in drinking water as a result of pipes, faucets, and other plumbing equipment made of lead. In soils, lead comes from paint, or landfills that contain waste from lead ore mining, ammunition manufacturing and from industrial activities. Since the 1920's, the largest source of lead in the atmosphere was the burning of gasoline (USDHHS, 1993). However, in the 1980's the U.S. Environmental Protection Agency (USEPA) limited the use of leaded gasoline in automobiles thereby decreasing emissions. Currently, sources of lead to the atmosphere include burning fuel, such as coal or oil, industrial processes and burning of solid waste.

Human exposure to lead can be particularly dangerous to young or unborn children since they are more sensitive to its effects. Health effects include premature birth or miscarriage in pregnant women, hearing problems, decreased IQ, and a retardation of physical growth in children. In adults, lead exposure can affect memory and decrease reaction time. In addition, exposure may cause or contribute to high blood pressure, anemia, and brain or kidney damage.

METHODS

Information contained in this report was generated through literature searches in libraries and on the World Wide Web. Data specific to the Ohio River Basin was obtained through personal communication and information requests with employees at federal, state and local government agencies. Agencies supplying information included the New York Department of Environmental Conservation, Pennsylvania Department of Environmental Protection, West Virginia Department of Environmental Protection, Ohio Environmental Protection Agency, Kentucky Division of Water, Indiana Department of Environmental

Management, Illinois Environmental Protection Agency, U.S Environmental Protection Agency Region 5, U.S. Geological Survey, U.S. Army Corps of Engineers, and ORSANCO. Sediment and fish tissue data, and their sources of contamination were compiled through the Toxics Release Inventory (TRI) database, STOrage RETrieval (STORET) database, Aerometric Information Retrieval System (AIRS), Permit Compliance System (PCS), and the CERCLIS database. Where possible, data was assessed for trends on a spatial and temporal scale in order to quantify changes in contamination within the Basin.

PHYSICAL AND CHEMICAL PROPERTIES

Lead is a bluish-gray, soft metal that exists in several naturally occurring and man-made forms in the environment (see Table 1). While many compounds contain lead, these substances

Lead Compounds	Chemical Formula
Metallic lead	Pb
Lead acetate	PbC ₄ H ₆ O ₄
Lead chloride	PbCl ₂
Lead bromide	PbBr ₂
Lead oxide	PbO
Lead phosphate	PbPO ₄
Lead sulfate	PbSO ₄
Lead sulfide	PbS
Tetraethyl lead	C ₈ H ₂₀ Pb

Table 1. Common lead compounds and their chemical formulas (USDHHS, 1993).

are not characteristic of lead in its metallic form. In its metallic form, lead is characterized as having a low melting point, high density, being insoluble in water, and lacking any characteristic taste or smell (see Table 2). Lead also readily tarnishes in the atmosphere but is considered one of the most stable fabricated metals because of its resistance to corrosion.

Property	Value
Molecular Weight	207.2
Melting Point	327.4 °C
Boiling Point	1,740 °C
Density	11.34 g/cm ³ @ 20 °C
Water Solubility	Insoluble
Vapor Pressure	1.77 mmHg @ 1,000 °C

Table 2. Summary of physical/chemical properties of lead (USDHHS, 1993).

The ultimate fate of lead in the environment is terrestrial or aquatic sediments. Typically, the accumulation of lead in soil is a function of the rate of deposition from the atmosphere. Once in the

atmosphere, lead exists primarily in the particulate form and can be carried long distances until it returns to the surface by wet or dry deposition. Approximately 40 to 70 percent of atmospheric deposition of lead is by wet fallout with the average residence time in the atmosphere being 10 days (USDHHS, 1993). However, an important factor in determining the atmospheric transport of lead is the particle size distribution. Large particles, with diameters greater than 2 um, settle out of the atmosphere fairly rapidly and are deposited relatively close to emission sources, whereas small particles may be transported thousands of kilometers (USDHHS, 1993).

In soil, lead sorbs strongly to organic matter with very little being transported into ground water or surface water. Typically, atmospheric lead is retained in the upper 2 to 5 cm. of soil when the pH is greater than or equal to 5, and there is at least five percent organic matter content. Depending on soil type and organic matter content, lead becomes immobilized by forming insoluble lead complexes or precipitating out with carbonate or phosphate ions. However, when the soil becomes acidic, or has a pH of between 4 to 6, leaching to groundwater can occur. Under natural conditions the downward movement of lead from soil to groundwater by leaching is very slow unless in a highly acidic environment, such as a National Priority List (NPL) site. In addition, inorganic lead is bound into crystalline matrices of rocks and remains essentially immobile.

Lead may enter rivers, lakes and streams when soil particles are displaced by rainwater and surface runoff. Lead can be present as sorbed ions or surface coatings on sediment mineral particles, or it may be carried as part of suspended living or nonliving organic matter in water. A significant fraction of lead carried by surface water is in the undissolved form and can consist of colloidal or larger-sized undissolved particles of lead carbonate, lead oxide, lead hydroxide or other lead compounds. Typically, the concentration of dissolved lead is low in groundwater and surface water because lead will form compounds with the anions in water, such as hydroxides, carbonates, sulfates and phosphates, and will precipitate out of the water column. The ratio of lead in suspended solids to lead in the dissolved form has been found to vary from 4:1 in rural streams to 27:1 in urban streams (USDHHS, 1993).

Once in the environment, lead remains there for many years. Some of the chemicals that contain lead can be broken down by sunlight, air and water to other forms of lead however, the lead atom itself cannot be broken down.

ENVIRONMENTAL AND HUMAN HEALTH CONCERNS

Even though lead occurs naturally, the majority of lead dispersed throughout the environment is primarily the result of anthropogenic activities. Environmental fate processes may transform lead from one compound to another however, it is not degraded and is still available for human exposure. Individuals can be exposed to lead through ingestion, inhalation or dermal contact. Typically, inhalation and dermal contact with lead are associated more with occupational exposure whereas, ingestion of lead is a concern to the general population. Individuals can be exposed to lead by eating lead-based paint chips, drinking water that comes from lead pipes or lead soldered fittings, breathing tobacco smoke, breathing or ingesting contaminated soil, dust, air or water near waste sites, eating contaminated food grown on soil containing lead, and breathing fumes or ingesting lead from hobbies that use lead, such as ceramics. Children, especially those who are preschool age, are at risk for potentially high levels of lead because of their tendency to put hands, toys and other lead containing items, such as paint chips, into their mouths.

The human body cannot distinguish between calcium and lead therefore, lead is assimilated in the bloodstream in the same manner as calcium. Once lead enters the body it is distributed in the blood to the "soft tissues", such as the liver, kidneys, lungs, brain, spleen, muscles and heart, and then transported to the bones where it can remain stored for decades and reenter the blood at a later time. The amount of lead remaining after storage is then removed from the body in urine and feces. Generally in adults, about 99 percent of the total amount of lead taken into the body is removed in wastes within a couple of weeks. However, since young children absorb more calcium to meet their extra needs, they also absorb more lead. Therefore, in children only 32 percent of the total amount of lead absorbed by the body is eventually removed (USDHHS, 1993). In all individuals, bone stores of minerals, including normally inert lead, can be mobilized back into the bloodstream and increase blood-lead levels at a later time.

Lead can affect almost every organ and system in the human body and health effects can last for months or years following exposure. At high levels, exposure to lead can cause permanent brain and kidney damage and impair the central nervous system by decreasing reaction time, causing weakness and aching in arms and legs, and possibly effecting memory. Other long-term effects from lead exposure include headaches, tiredness, irritability, stomach problems, and anemia. In middle-aged men, exposure to lead at high levels may increase blood pressure and affect the male reproductive system. Lead is also particularly toxic to children and fetuses. High level exposures may cause miscarriages, premature births, smaller birth weights, reduced growth rates, and decreased mental ability. The relationship between lead exposure in humans and increased cancer risk is still uncertain. Based upon occupational exposure studies, there is insufficient scientific data necessary to link lead exposure in humans to cancer. However, some laboratory animals being fed high-levels of lead have developed kidney tumors.

Plants and animals may accumulate lead but biomagnification, or an increase in concentration through the food chain, has not been detected. In aquatic organisms, lead concentrations are usually highest in benthic organisms and algae, and lowest in upper trophic level predators. However, lead is toxic to all aquatic biota, and organisms higher on the food chain may experience lead poisoning as a result of eating lead-contaminated food.

The U.S. Environmental Protection Agency (USEPA) does not designate a Maximum Contaminant Level (MCL) for lead in drinking water since its primary source is from corrosive pipes in the water distribution system. Rather, the USEPA established a Maximum Contaminant

Level Goal (MCLG) at 0 ug/L for lead in drinking water (see Table 3). A MCLG is a nonenforceable health goal set at a level to prevent known or anticipated adverse effects with an adequate margin of safety. Whereas, an MCL is an enforceable standard that is set to be as close to the MCLG as is feasible based upon water treatment technologies and cost. In addition, the USEPA established an Action Level which prohibits lead concentrations to exceed 0.015 mg/L in drinking water at the tap. The Action Level encourages public water systems to decrease contamination from plumbing and reduce lead levels as close to MCLG as possible.

To protect the biological community, USEPA has established chronic and acute criteria for lead to protect against long-term toxicity to aquatic life. These values are based upon a hardness of ambient water equaling 100 mg/L and represent the highest in-stream concentrations of lead to which organisms can be exposed infinitely without causing harmful effects. In addition, there is a Median International Standard (MIS) for lead in fish tissue at 1.75 ppm. The MIS does not apply in the United States, however it is an indication of the concentration of lead in fish tissue that is considered unsafe by the international community.

Regulatory Standards and Criteria	Value
U.S. EPA Action Level in Drinking Water	15 ug/L (ppb)
U.S. EPA Ambient Water Quality Criteria for the Protection of Human Health	0.05 mg/L (ppb)
U.S. EPA Ambient Water Quality Criteria for the Protection of Aquatic Organisms/ ORSANCO Criterion for the Protection of Aquatic Life	82 ug/L (Acute) 3.2 ug/l (Chronic)
U.S. EPA Drinking Water Standards	0 mg/L (MCLG))
Median International Standard in Fish Tissue	1.75 ppm

Table 3. Summary of national and interstate regulations pertaining to lead (USDHHS, 1993).

FORMATION AND SOURCES

Lead is produced either through mining operations or recovery from secondary sources, such as batteries. Currently, in the United States there are 16 underground lead-producing mines of which, 99 percent are located in the states of Missouri, Alaska, Idaho and Montana (U.S. Department of the Interior, 1995). Mined or recycled lead can be used in the form of metal, either pure or alloyed with other metals, or in chemical compounds.

As of 1995, domestic uses for lead were broken down into three major categories which include: transportation, electronics and other (see Figure 1). Nationally, the largest end-use for lead is in the transportation industry and includes the manufacturer of batteries, fuel tanks, solder, seals and bearings. Within this classification, lead-acid batteries are the dominant use of lead, accounting for about 84 percent of this category. The second largest use for lead is in the electronics and communication industries and includes uses such as ammunition, TV glass, electrical and electronic components and accessories, and protective coatings. The remaining 7 percent of lead consumption includes production of ballasts and weights, ceramics and crystal glass, type metal, foil, wire and specialized chemicals (U.S. Department of the Interior, 1996).

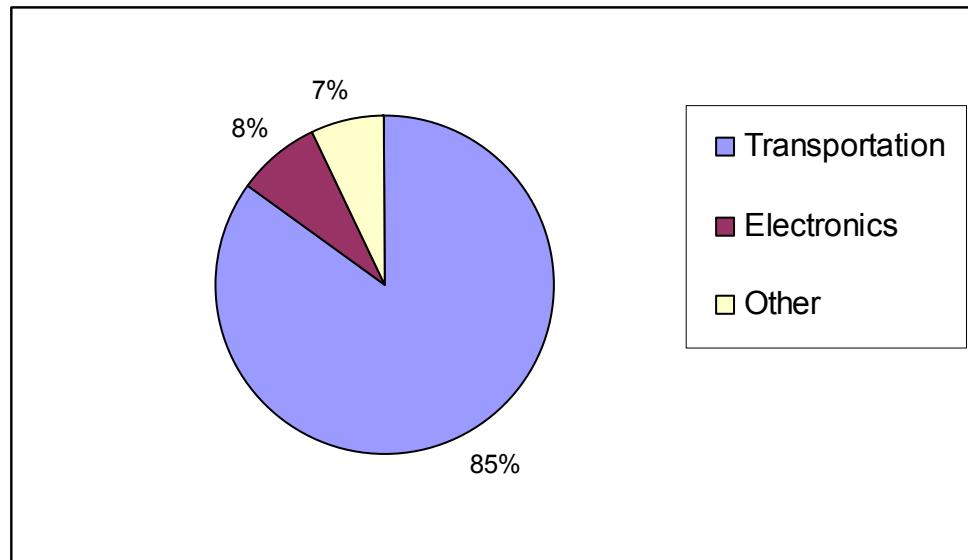

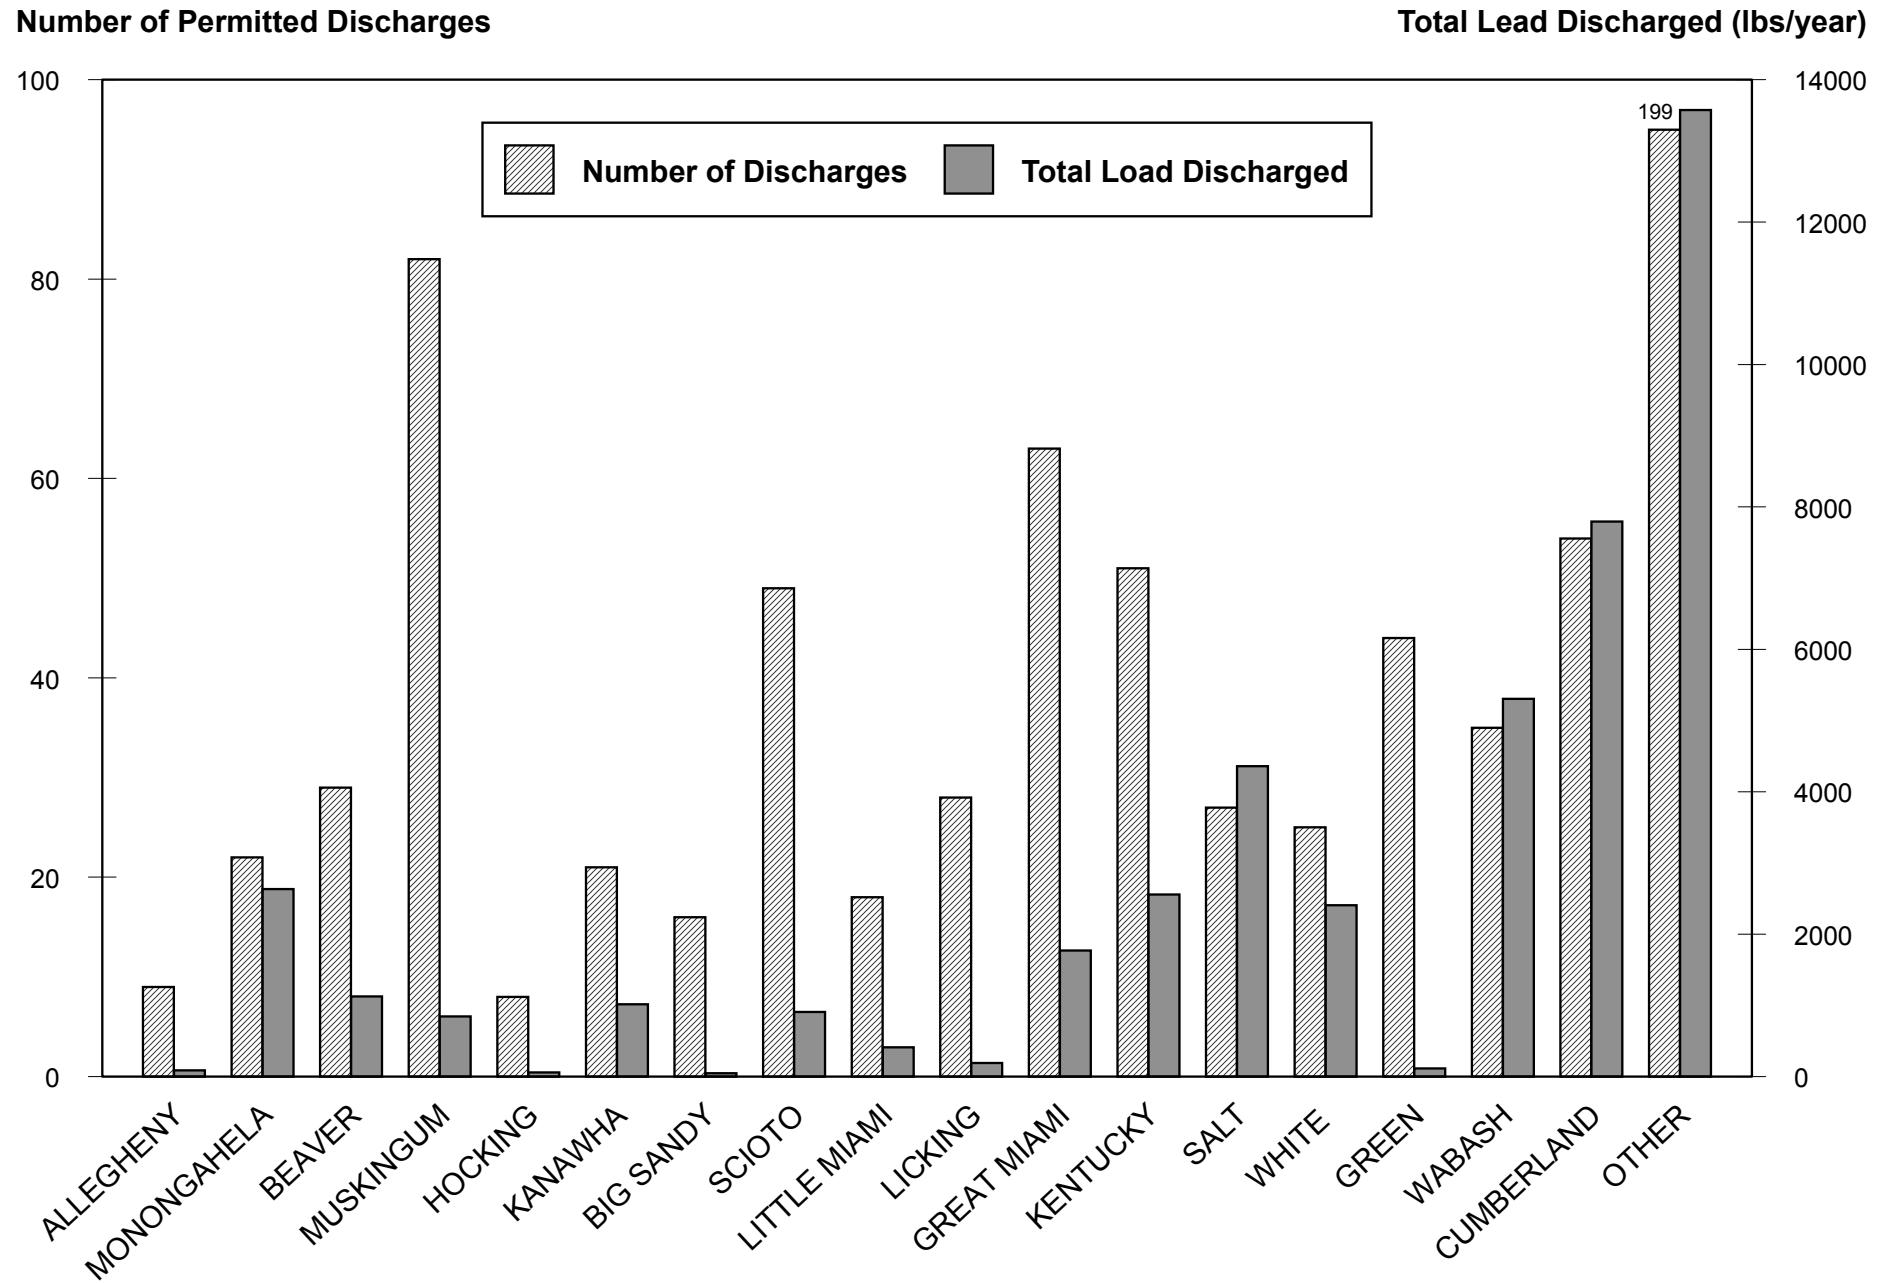

Figure 1. 1995 United States lead consumption (U.S. Department of the Interior, 1996).

In recent years, the amount of lead added to paints and ceramic products, caulking, gasoline additives and solder has decreased due to potential human health and environmental impacts. Major sources of lead in drinking water include lead pipes, faucets, and solder found in houses, schools and public buildings. In surface water and soil, sources of lead include deposits of lead-contaminated dust in the atmosphere, wastewater from industries that handle lead (primarily iron and steel industries and lead producers), and urban runoff (USDHHS, 1993a). Lead can also be released to soil from lead-contaminated wastes in municipal and hazardous waste landfills, fertilizers that contain sewage sludge, and from the weathering and deterioration of lead-based paint. Until recently, the largest single -source of lead in air was vehicle exhaust. However, as of December 31, 1995 it has been illegal to sell leaded gasoline (USDHHS, 1993a). Other sources of lead to the atmosphere include cigarette smoke, emissions from iron and steel production, smelting operations, lead-acid battery manufacturers, municipal waste incinerators, volcanoes, burning or weathering of lead-painted surfaces, and windblown dust.

In 1996, the National Pollutant Discharge Elimination System (NPDES) contained 808 permitted facilities that monitored for or discharged lead in the Ohio River Basin (PCS, 1997). The discharges accounted for approximately 45,850 pounds of lead in the Ohio River and its major tributaries (see Appendix A). Overall, the largest contribution of lead in the Basin was from direct discharges to the Ohio River and many of its smaller tributaries (see Figure 2). This accounted for over 13,500 pounds of lead in the Basin, representing almost 30 percent of the total load. Comparing discharges from major Ohio River sub-basins, the largest loadings originated from the Salt River, Wabash River, and Cumberland River sub-basins with over 4300 pounds, 5300 pounds, and 7700 pounds of lead respectively (see Figure 3).

Nationally, lead has been identified in at least 922 of 1,300 hazardous waste sites that have been proposed for inclusion in the U.S. EPA's National Priorities List (NPL). The NPL is U.S. EPA's list of uncontrolled or abandoned hazardous waste sites identified for possible longterm cleanup under the Superfund Program. Within the Ohio River Basin, 46 NPL sites have been identified with either lead or heavy metal contamination (see Figure 4). Of these *potential* sources, 65 percent are former industrial waste landfills or disposal facilities that have lead contamination in the soil (see Appendix A).

**Figure 2. NPDES Summary for Lead in the Ohio River Basin
1996**

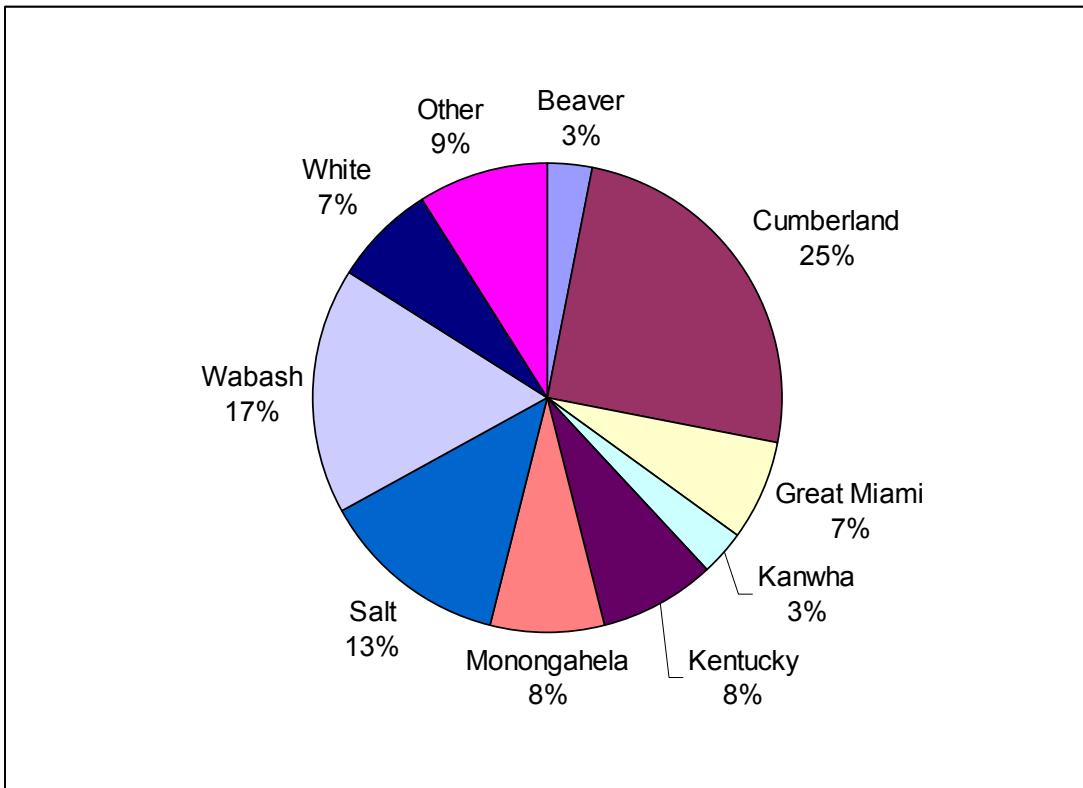

Figure 3. 1996 Percentage of lead loading by major Ohio River sub-basins (PCS, 1997).

Based upon U.S. EPA's Toxic Release Inventory (TRI) over 250 industries have been identified as *potential* sources of lead in the Ohio River Basin between the years 1990 to 1994 (see Figure 5). The TRI is a listing of facilities that are required to report on releases of toxic chemicals into air, water, and land. A facility is required to report to the TRI if it has ten or more full-time employees; uses more than 10,000 pounds of any designated chemical or category; and it conducts manufacturing operations in the groups specified by the U.S. Government Standard Industrial Classification (SIC) Codes 20 through 39 (USEPA, 1996). In 1994, over 50 of these industries reported direct releases of lead, totaling more than 12,000 pounds, into the Ohio River and/or its tributaries (TRI, 1996). In addition, all of these facilities, whether releasing or not, use large quantities of lead onsite for their manufacturing processes (see Appendix A).

PRESENCE IN THE OHIO RIVER BASIN

Data on the presence of lead within the Ohio River Basin is extensive. To date, information has been collected from aqueous, fish tissue, and sediment samples on the mainstern of the Ohio River and many of its tributaries. In addition, atmospheric data was obtained from various locations within the basin.

**Figure 4. National Priority List Sites with Lead Contamination
in the Ohio River Basin***

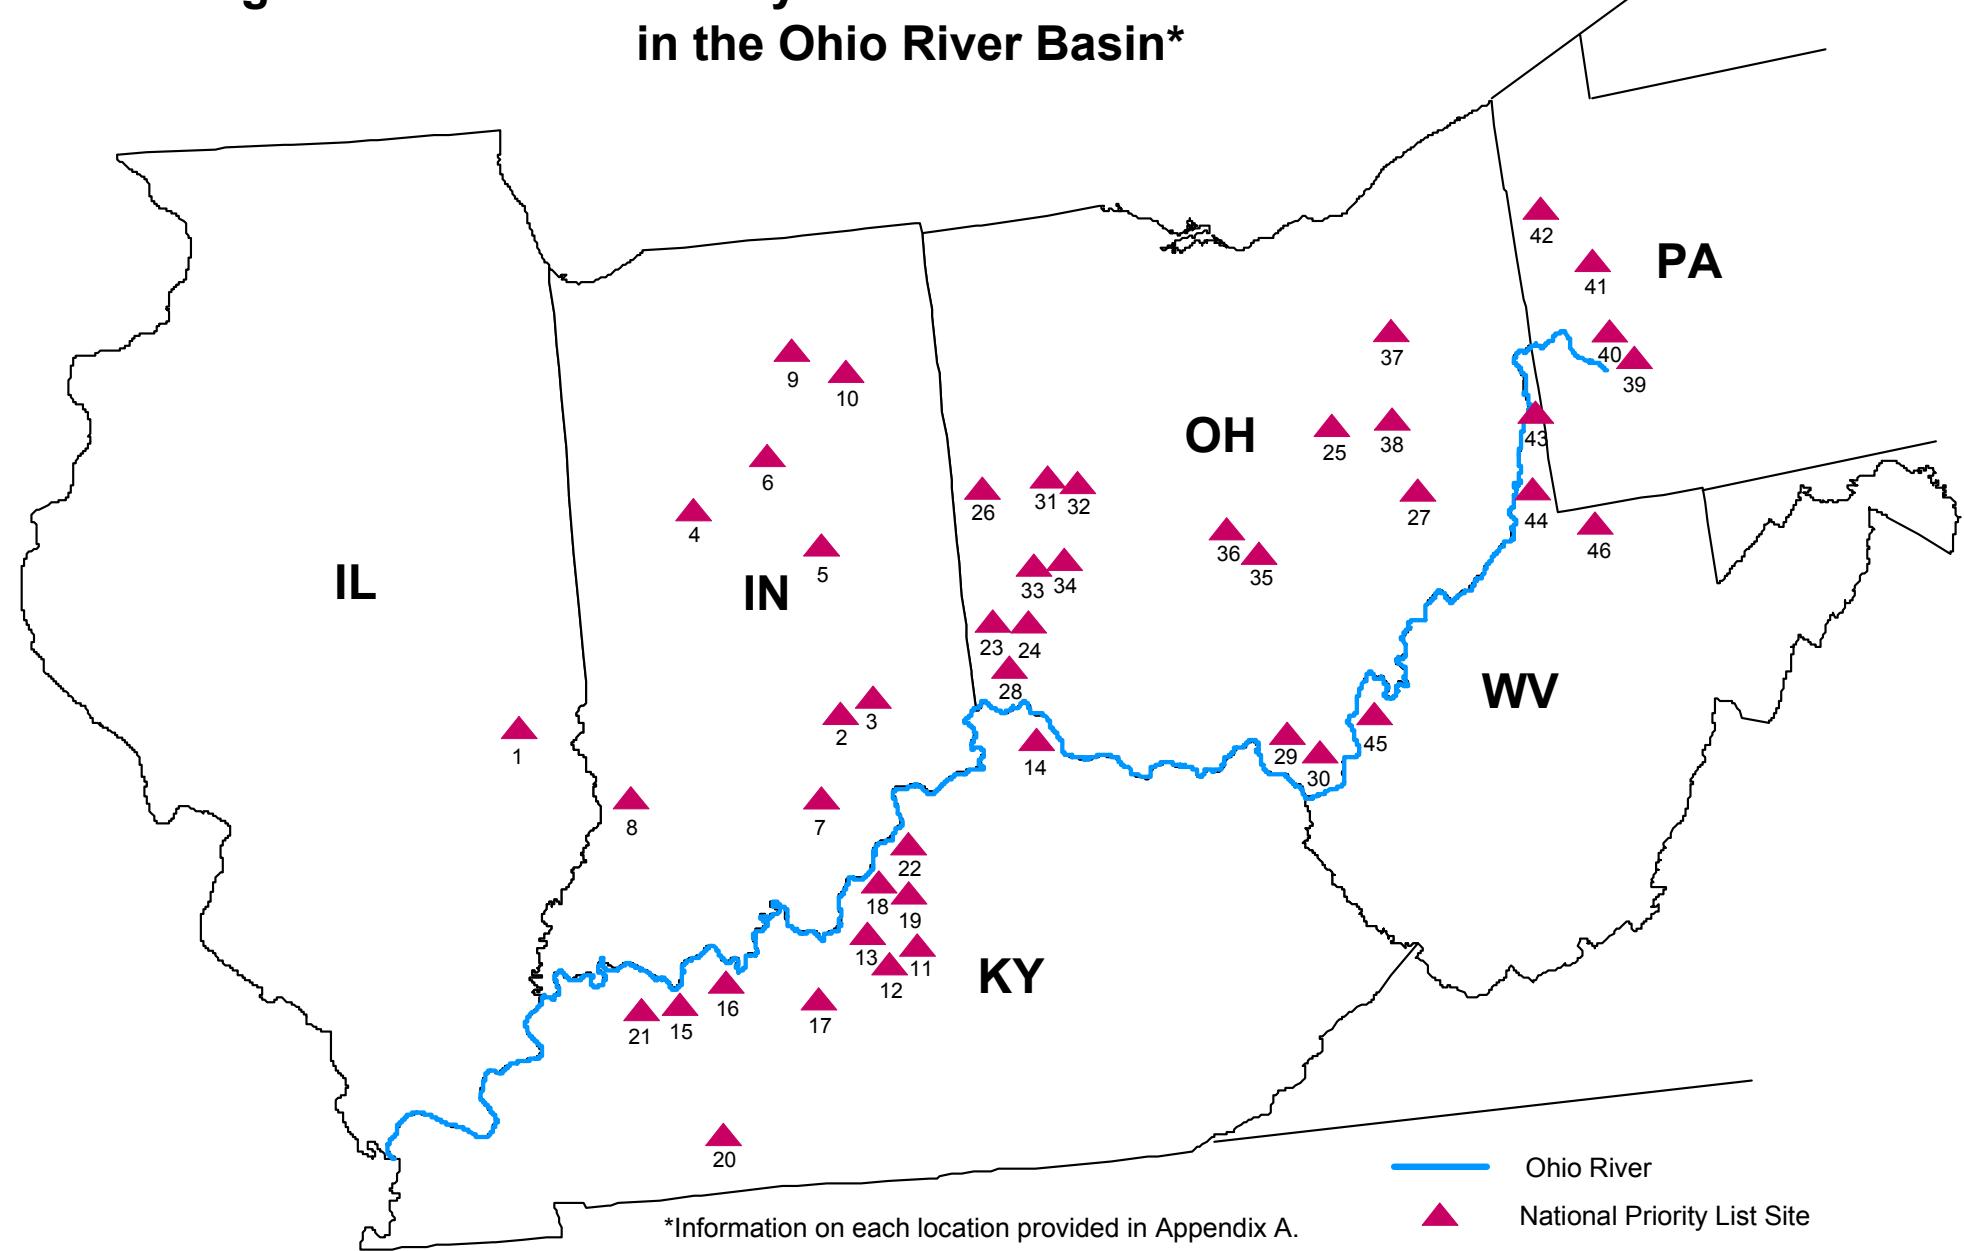

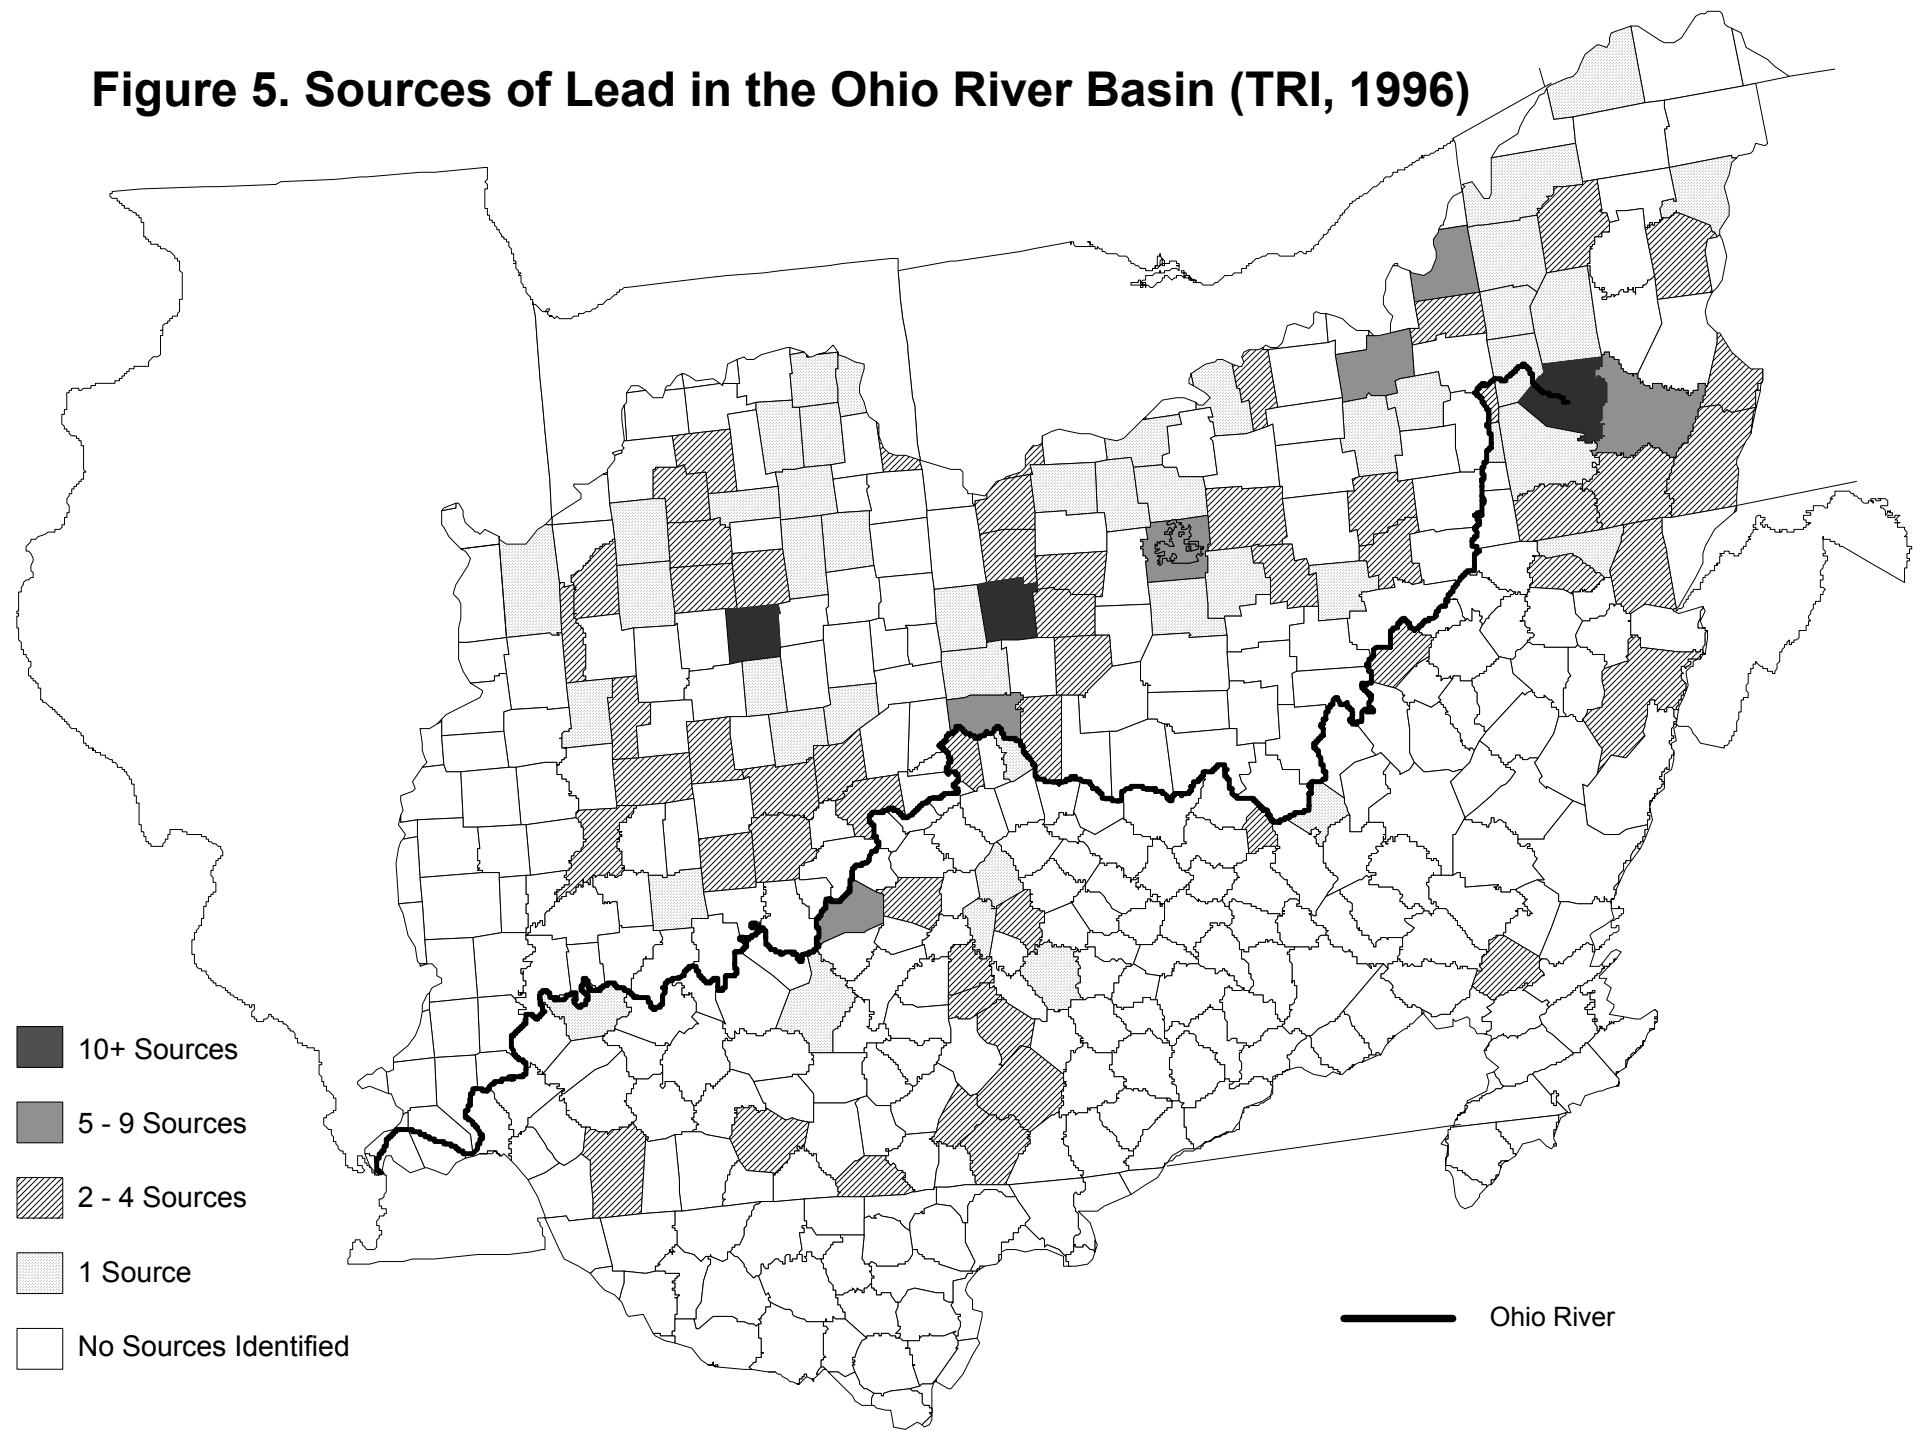

Figure 5. Sources of Lead in the Ohio River Basin (TRI, 1996)

More than 60 percent of bimonthly ambient water samples, collected by ORSANCO at fourteen Ohio River locations between 1992-1997, were at or below laboratory detection levels for total lead (see Appendix B). Out of the samples that were collected over the six-year period, 23 percent violated ORSANCO's Chronic Aquatic Life Criterion for lead in surface water while none exceeded the acute criterion (see Table 4). Out of all the monitoring locations, Ohio River miles 625.9 and 918.5 recorded the most Chronic Criterion violations with 10 and 12, respectively.

Comparisons made between lead loading at different Ohio River locations indicate an increasing longitudinal trend. From the headwaters of the Ohio River at Pittsburgh, to its mouth near Paducah, Kentucky, average loads increased by more than 12,000 pounds per day of total lead (see Figure 6). However, on a temporal scale it appears that the overall loading in the Ohio River decreased from 1990 to 1997 (see Figure 7). In 1990, average loading was approximately 22,000 lbs/day of total lead compared to about 2,800 lbs/day in 1997, representing an 87 percent decrease in Ohio River lead loads.

Ohio River Mile	Number of Samples Collected	Chronic Criterion Violations
54.4	30	7
84.2	30	5
161.8	33	7
203.9	33	7
436.2	30	1
477.5	30	6
531.5	33	8
606.8	27	7
625.9	30	10
720.7	29	7
776.1	26	5
846	29	6
918.5	27	12
938.9	21	5

Table 4. Ohio River bimonthly water samples that exceed ORSANCO's Chronic Criterion Concentration (ORSANCO, 1998).

Monitoring data from fourteen major Ohio River tributaries indicates that the Little Miami River contributes the smallest loading of lead to the Ohio River with an average of about 122 lbs/day (see Figure 8). The Wabash, Cumberland, Kanawha, Allegheny, and Green Rivers appear to contribute the largest lead loading to the Ohio River with approximately 2300 lbs/day, 1900 lbs/day, 1700 lbs/day, 1200 lbs/day, and 1100 lbs/day respectively (see Appendix B). Furthermore, 80 Chronic Criterion violations

Figure 6. Average Longitudinal Distribution of Lead Loading in the Ohio River*
1992-1997

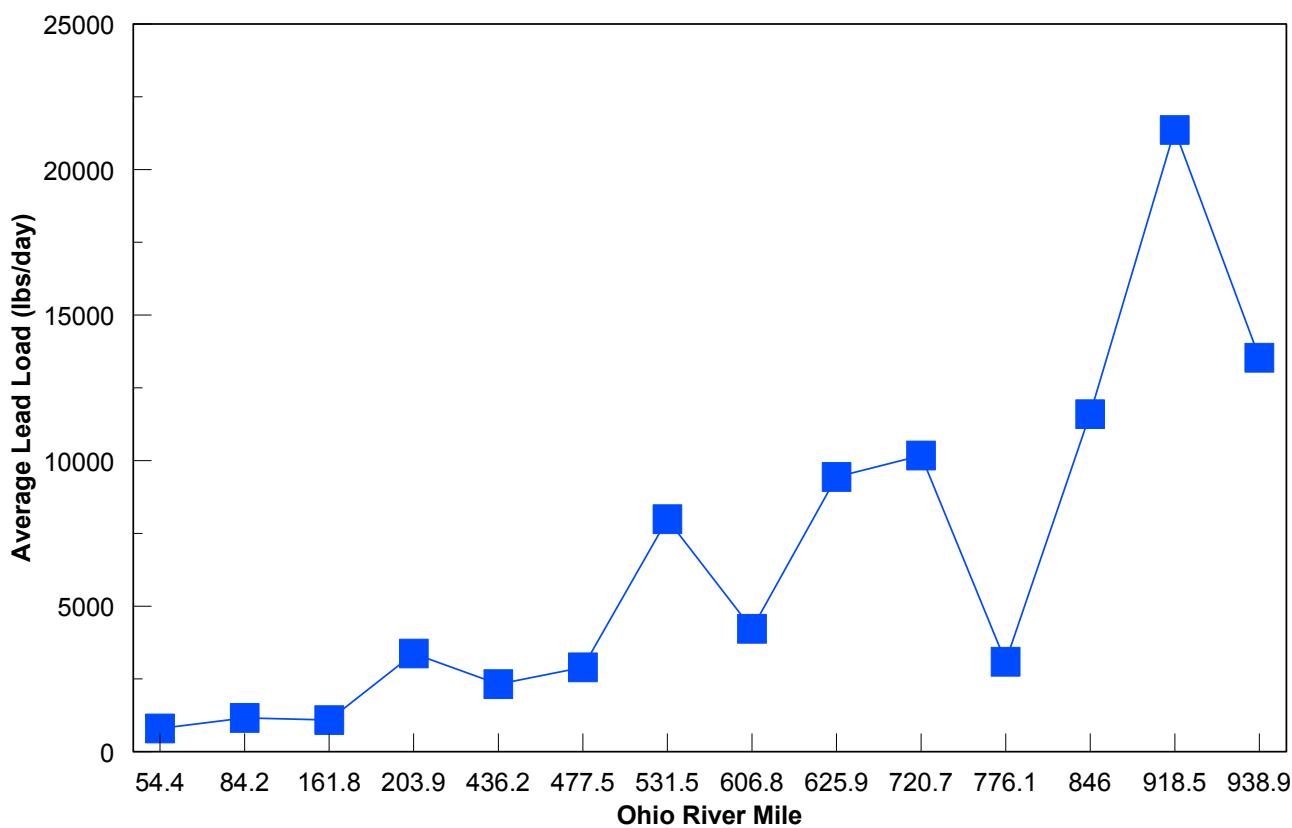

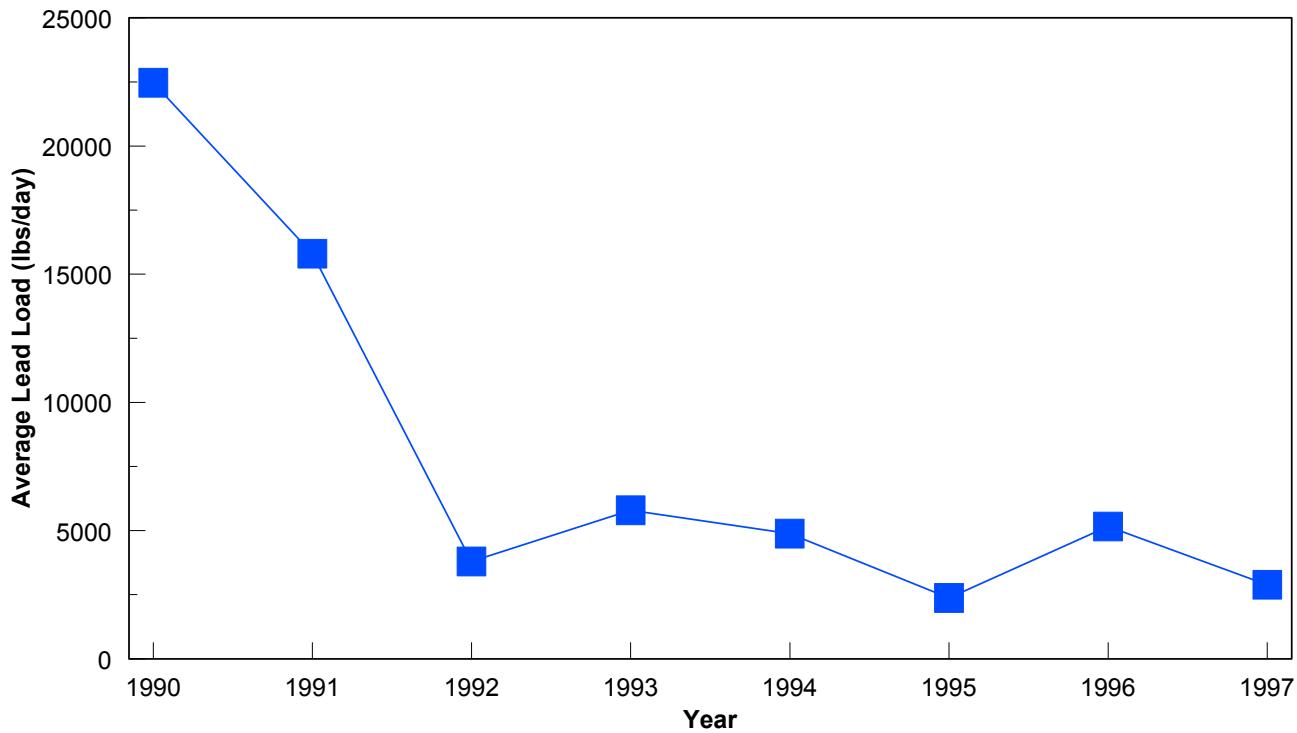

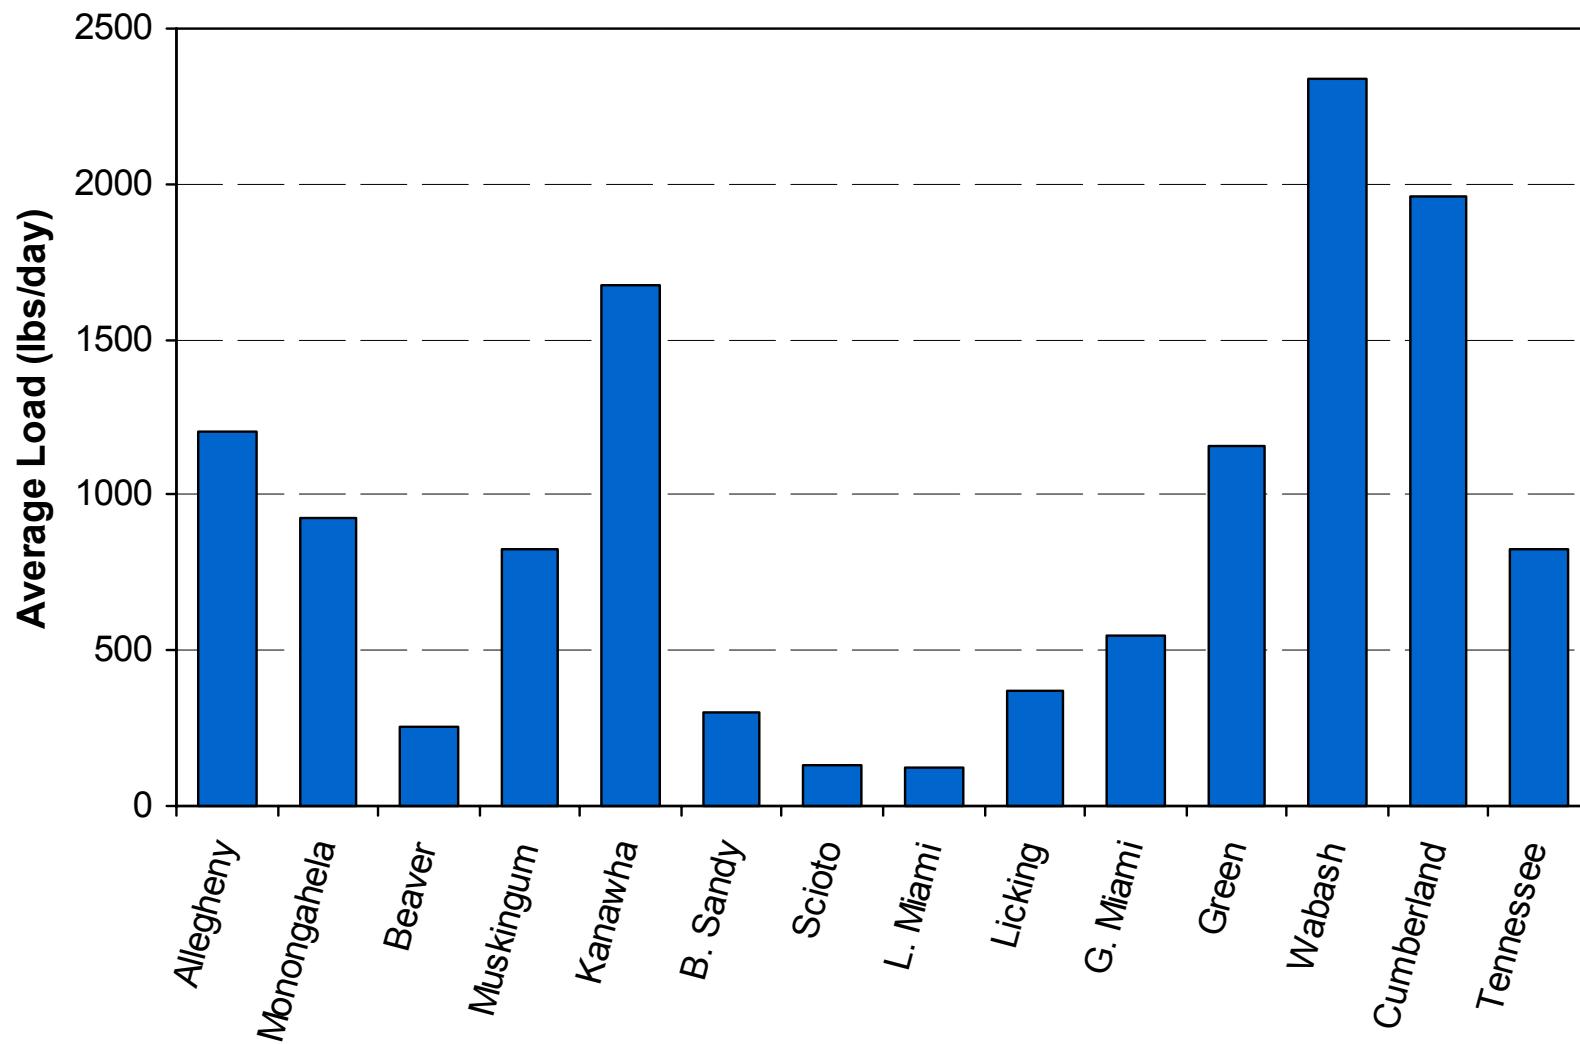

Figure 7. Average Annual Distribution of Lead Loading in the Ohio River*
At All Locations

*Half the detection concentration was used for samples at the detection level.

**Figure 8. Average Lead Loading from Major Tributaries
to the Ohio River, 1992-1997**

for lead were recorded on the major Ohio River tributaries between July 1, 1992 to December 31, 1997. The largest number of Chronic Criterion violations were reported on the Kanawha and Cumberland Rivers, with eleven violations each, while the Green and Wabash Rivers had the lowest number of violations with one on each tributary.

Dissolved and total lead concentrations retrieved through STORET, from 1980 to 1996, are primarily at or below detection limits for surface waters in the Ohio River Basin (see Appendix B). Some samples were collected at relatively high concentrations in the Saline River, Tradewater River, Kentucky River, Wabash River, Jamison Creek, Wildcat Creek, and several smaller unnamed tributaries. However, trends in dissolved and total lead concentrations are not evident. A similar situation exists for sediment data collected by state agencies and the U.S. Army Corps of Engineers (see Appendix B). Several sewage treatment plants in Kentucky (Jeffersontown, London, and Town Branch) had samples with relatively high total lead concentrations in sediment but trends were not evident.

Fish tissue samples collected by ORSANCO in the Ohio River between 1992-1994 are also inconclusive in terms of trends in lead concentrations. Greater than 60 percent of the samples collected were at or below detection levels for total lead in fish tissue. The Ohio Environmental Protection Agency (OEPA) has established a fish tissue database for samples collected on portions of the Ohio River and several of its major tributaries (see Appendix B). While the majority of samples collected for lead between 1994 to 1996 were below detection levels, about 25 percent of the samples exceeded 50 ppb. In addition, relatively high concentrations of greater than 500 ppb were collected from both the Great Miami River and Mahoning River.

Atmospheric data, retrieved from the Aerometric Information Retrieval System (AIRS) from 1992 to 1997, indicate quarterly average concentrations for lead are relatively low within the Ohio River Basin (See Appendix B). During this period only three exceedences to the National Ambient Air Quality Standard (NAAQS) of 1.5 ug/m³ were reported to the U.S. EPA. In these instances, all violations are low level detections that occurred in Indianapolis, IN, between 1993 and 1994.

CONTROL PROGRAMS

In order to reduce lead concentrations in drinking water, the U.S. EPA requires water system authorities to install or improve corrosion control measures to minimize lead levels at the tap while ensuring that treatment does not cause the water system to violate any national primary drinking water standards. These measures include corrosion control treatment, source water treatment, public education, and lead service

line replacement when targeted tap samples continue to exceed the action level for lead in drinking water (USEPA, 1995).

CONCLUSIONS

- Lead is found naturally within the earth's crust but human activities have spread it to all parts of the environment.
- Lead does not degrade though it can be transformed from one form to another.
- Over 800 permitted discharge sources of lead exist to surface waters within the Ohio River Basin accounting for approximately 45,800 lbs/year of total lead.
- The Wabash, Cumberland, and Tennessee Rivers account for the greatest point source lead loadings to the Ohio River.
- Lead loading increases by more than 12,000 lbs/day from the headwaters of the Ohio River to its mouth.
- Approximately 2 percent of the total lead load discharged from the Ohio River is attributed to point sources.
- Major tributary sources of total lead to the Ohio River include the Allegheny River, Kanawha River, Green River, Wabash River, and Cumberland River.
- The majority of fish tissue data within the Basin are below detection levels but a few samples exist at relatively high concentrations in the Great Miami River and Mahoning River.
- Atmospheric concentrations of lead are relatively low within the Ohio River Basin.

U.S. Army Corps of Engineers Sediment Data

Station names are derived from river mile and percent distance from the left decending bank

Example: OR33899

Ohio River Mile = 338.99

Percent distance from left bank = 90%
