## Introduction

Based in Cincinnati, the Ohio River Valley Water Sanitation Commission (ORSANCO) is an interstate water pollution control agency created in 1948 by an act of Congress to monitor and improve the water quality of the Ohio River. A primary goal of ORSANCO programs is to work with state agencies to develop a set of pollution control standards for the Ohio River. Monitoring programs were established to develop and refine these standards. One of these programs, the ORSANCO biological program, uses fish studies to establish biological criteria (biocriteria) for the Ohio River. These biocriteria are ultimately used to provide insight into the overall health of the river ecosystem.

In 1993, ORSANCO developed and implemented a survey design that used electrofishing methods designed for the Ohio River. After years of collecting fish population data on the Ohio River, we developed the original Ohio River Fish Index (ORFIn) which was subsequently modified (mORFIn). Each year we collect fish and environmental data from various sections of the Ohio River and use these data to calculate mORFIn scores, which are numerical representations of the relative condition of Ohio River fish communities based on a suite of measurable attributes. The resulting scores allow us to assess the biological condition of each section of the river. The information included in these assessments is further used for regulatory, restorative, and protective efforts within the Ohio River basin.

1948 - ORSANCO is created to, among other things, ensure the Ohio River is "capable of maintaining fish and other aquatic life"

How our achievements coincide with national milestones in the effort to restore our nation's water

1969 - The Cuyahoga River catches fire, fueling the movement to clean our nation's water continued nearly each year until 2005. These data comprise one of the most comprehensive river fisheries databases in existence

> 1964 - We begin monitoring aquatic bugs (macroinvertebrate) populations in the Ohio River

1975 - With the aid of several partners, we begin to sample fish tissue as a means for determining the presence or absence of certain pollutants

1987 - Fish tissue procedures are modified \& refined allowing appropriate state agencies to use the data for fish consumption advisories

1993 - We institute a semi-random sampling design allowing us a more unbiased means to assess Ohio River fish communities
2003 - The Ohio River Fish Index (ORFIn) is created

2005 - We begin routine surveys employing the ORFIn and random design, and a macroinvertebrate methods comparison study

2008 - The ORFIn is further refined \& modified creating the mORFIn

2012 - The Ohio Rive Macroinvertebrate Index (ORMIn) is created 2015 - Refined ORMIn included in annual assessments

## fish

1957 - With the aid of mulitple populations from Ohio River lockchambers, an effort that would be

1970 - The Environmental<br>Protection Agency (EPA) is created<br>1972 - The first incarnation of the Clean Water Act, the Federal Water Pollution Control Amendments, lays the foundation for more rigorous future legislation

> 1977 - The Clean Water Act (CWA) is passed with the goal to greatly reduce sources of water pollution
> 1987 - The Water Quality Act is amended to the CWA. One of its goals, to "restore the biological integrity of the nation's waters," emphasized the need for tools like the ORFIn
> 1990 - EPA initiates the Environmental Monitoring \& Assessment Program (EMAP) to assess the nation's water bodies. We participate in regional surveys of Ohio River tributaries conducted between 2004 -2006

Present - We continue to work with state \& federal agencies to assess the biological integrity of Ohio River aquatic communities as directed by the Clean Water Act

This report summarizes the 2019 R.C. Byrd and Smithland pool assessment survey findings.

## The River

The Ohio River begins at the confluence of the Monongahela and Allegheny rivers in Pittsburgh, PA and flows 981 miles in a southwesterly direction to its confluence with the Mississippi River near Cairo, IL. The Ohio has several additional large tributaries including the: Muskingum, Scioto, Kanawha, Kentucky, Green, Wabash, Cumberland and Tennessee rivers. The Ohio River itself runs through or borders six states; Illinois, Indiana, Kentucky, Ohio, Pennsylvania, and West Virginia. The river basin ( $>200,000 \mathrm{mi}^{2}$ ) covers an additional eight states: New York, Maryland, Virginia, North Carolina, Tennessee, Georgia, Alabama, and Mississippi. Nineteen high-lift locks and dams maintain a nine-foot minimum depth for commercial navigation throughout the river.

## Facts

- Average depth 24 ft , max depth exceeding 90 ft
- Average width $1 / 2 \mathrm{mi}, 1 \mathrm{mi}$ max (Louisville, KY)
- $\quad$ 344 fish species from Ohio River basin (18 exotic) $=$ $40 \%$ of known N. American species ( 800 species)
- ~178 fish species found in the Ohio River (14 exotic)
- Deciduous forests continue to dominate the basin
- Major land uses: pastures, row crops, and urban development
- Basin holds $\sim 8 \%$ of the nation ( 27 million people)
- 33 drinking water intakes provide drinking water for over 5 million people along the main stem
- 589 permitted discharges to the Ohio River
- 49 power-generating facilities on the main stem
- Coal and energy products comprise $70 \%$ of the 250 million tons of cargo carried by barges each year

## METHODS

## Site Selection

A random, probability-based survey design was used to select sampling site locations within each Ohio River navigational pool. The target areas of our surveys are both shorelines of each pool from the upstream dam to the downstream dam. The survey design provides coordinates for 15 sites (500m-long) in each of the selected pools. Biological and environmental data are then collected from these 15 sites and used to assess the biological condition of the pool.

## Fish Collection

To maintain consistency across different sampling years, fish surveys are conducted between July $1^{\text {st }}$ and October $31^{\text {st }}$ and when water levels are within two feet of "normal flat pool". Fish are collected by a non-lethal method called boat electrofishing using an 18 ft aluminum johnboat equipped with a generator and an electrofishing unit (standard equipment used by federal and state agencies). Using the electrofishing unit to regulate the output from the generator, a mild current is applied to the water with an effective range of up to 20ft. Because of our limited range, sites are fished at night along the shoreline when species are most active. This allows us to maximize the number of individuals and species captured, thus providing us with an accurate representation of the fish community at each site.

[^0]
## Collecting Macroinvertebrates

Macroinvertebrates (macros) are organisms that lack a true backbone and can be seen with the naked eye. They include aquatic insects, molluscs, arachnids, crustaceans and worms. They can range from large adult forms (e.g. crayfish), to very small larval forms of terrestrial insects (e.g. flies).

Two sampling methods are used to collect macroinvertebrates (macros): Hester-Dendy (HD) samplers and multi-habitat kicks (MH). HD samplers are constructed of tempered masonite cardboard cut into 3 in square plates and 1in square spacers. Eight large plates and 12 spacers are stacked on a metal eyebolt to provide varying degrees of space for macro colonization. Five HDs are attached, in a ring, to a concrete paver. The paver is then placed on the river bottom in 10ft of water at the downstream end of each 500 m sampling site and secured to the shore. Similar to the fish, macro sampling is restricted to a defined season within each year. HDs are deployed for six weeks, beginning September $1^{\text {st }}$ allowing adequate time for macro colonization. After the six week colonization period, HDs are retrieved and MH kick surveys are conducted.

A MH kick is performed by actively disturbing the substrate and then sweeping a net through the resulting cloud. This technique allows the sampler to collect macros without compromising the sample with large amounts of sediment. To further exclude sediments, the net heads are " $D$ " shaped (i.e. have flat bottoms), which also eases the scraping of woody debris and boulders. Samplers disturb/scrape 10 linear meters of substrate at each 100 m interval of a site in depths 1 m or shallower. At each of these intervals, every
attempt is made to sample available habitats (e.g. sand flats, woody debris, boulders, etc.) relative to the proportion of their availability. The kicks conducted at each 100 m interval are then combined to represent the community present at the site.

Once the kicks are completed and the HDs have been retrieved, the samples are preserved. The HDs are disassembled in the field. The plates from the HDs and large debris from the MH samples are rinsed and drained through a $500 \mu \mathrm{~m}$ sieve. The macros trapped by the sieve are then transferred to a preservative jar with $70 \%$ ethanol to be identified in a laboratory. At the lab, macros are identified to species level when possible; in all other cases the highest level of taxonomic resolution is obtained. The macro information is then reviewed and imported into a database from which index scores are generated, keeping HD and MH data separate.

## Characterizing Instream Habitat

Intensive habitat surveys are conducted which include measures of woody cover, depth, prevalence of substrate types at each electrofishing site. Woody cover (e.g. submerged brush, logs, stumps) is estimated visually. More quantitative measures of depth and substrate proportions are obtained through the use of a $20^{\prime}$ copper pole. The pole is used to probe the bottom of the river to determine exact depth and the proportions of substrate types including: boulder, cobble, gravel, sand, fines, and hardpan (clay) that occur at each site.

Because different fish species prefer different habitat types, it is important to classify the instream habitat at each of our sites to better understand mORFIn score variability. Using the habitat survey data, we assign each site to one of five statistically derived habitat classes simply named: $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$ and E . The five habitat classes represent a gradient from highly coarse
 Class A habitats with high amounts of cobble and gravel, to the predominantly sandy/fine substrates of habitat classes "D" and "E" which differ by water depth (see below).

## Water Quality and Hydrology

Basic measures of water quality such as water temperature, clarity, $\mathrm{pH}, \mathrm{DO}$, and conductivity are measured at each site prior to electrofishing. Water samples may also be collected at the downstream end of each 500 m zone approximately 100ft from shore to determine various water quality parameters (e.g. nutrient levels and hardness). River stage is monitored using data obtained from the U.S. Army Corps of Engineers, who also provide measures of predicted daily average flow volumes and velocities from the nearest-upstream sampling station to any particular site. These data are compiled to aid in the interpretation of the fish index results.

## A look at our five habitat classes

## Assessing Biological Condition

ORSANCO uses two biological indices to assess the condition of the Ohio River. The modified Ohio River Fish Index ( $m$ ORFIn) and the Ohio River Macroinvertebrate Index (ORMIn using HD data only) were established in 2003 and 2012, respectively. Both indices include various measures (metrics) of the fish and macro communities such as: diversity, abundance, feeding and reproductive guilds, pollution tolerance, habits, health.

\left.| 13 metrics used to generate mORFIn scores |  |
| :--- | :--- |
| Fish Metric | Definition |\(\right\left.] \begin{array}{ll}Native Species <br>

Intolerant Species\end{array} \quad $$
\begin{array}{l}\text { Number (No.) of species native to the Ohio River } \\
\text { No. of species intolerant to pollution and habitat } \\
\text { degradation }\end{array}
$$\right]\) No. of sucker species (e.g. redhorse and buffalo)

Each navigational pool is separately assessed with each index based upon the biological and environmental data collected from its 15 randomly selected sites. This involves a multi-step approach (depicted top right) that converts average metric scores ( $0-100$ ) of each individual site into final index scores (0-60), based on varying expectations of the five different habitat classes. Index scores of the 15 sites are then averaged to provide an overall score and rating for the navigational pool specific to each index.

The presence of five distinct habitat classes A, B, C, $D$ and $E$, coupled with the range of habitat preferences exhibited by individual fish and macro taxa required the translation of metric scores into relative index scores. By removing the effect of habitat, index scores can then be averaged within a pool to represent the overall condition of the biological community in question.

The averaged scores for both the mORFIn and ORMIn are then compared to a biocriterion. The $25^{\text {th }}$ percentile is the statistical threshold commonly used by regulatory agencies for establishing biocriteria. Using this threshold, our established biocriterion (i.e. a representation of healthy Ohio River fish communities) is set at an average index score of 20.0.

A pool is assessed to be in full support of its aquatic life-use (ALU) designation (i.e. possessing intact biological communities) if both the mORFIn and ORMIn scores are greater than or equal to 20.0 (i.e. a biological rating "Fair", "Good", "Very Good", or "Excellent"). A pool is in partial support of its ALU designation if only one of the indices' scores greater than or equal to 20.0, while the other index score falls within 10.0-19.9 (i.e. a "Poor" rating). Any pool in which both indices score below a 20.0, or in which at least one index scores below 10.0 (i.e. a "Very Poor" rating), would be considered in non-support of its ALU designation.

For more detailed information pertaining to our programs including survey design, field methods, past \& present assessment results, or biological data contact one of our staff or visit: www.orsanco.org/biological-programs

## 2019 Pool Survey Results

The results of the 2019 biological surveys are detailed in the following pages (relative pool locations shown below). Included are brief descriptions of the land use \& hydrology, site level mORFIn \& ORMIn ratings, summaries of notible catches \& instream habitat, and the overall biological condition of each pool.

For more detailed catch, metric, and index scores visit www.orsanco.org/programs/biological-programs

## R.C. BYRD POOL (2019) - Healthy Condition

R.C. Byrd pool is 41.7 miles long, extending from Racine Locks and Dam (ORM 237.5) to R.C. Byrd (formerly Gallipolis) Locks and Dam (ORM 279.2). The pool has a gradient drop of 0.6 feet per mile and averages 1,154 feet wide and 26 feet deep (ORSANCO 1994). The pool is bordered by West Virginia and Ohio. This pool lies in a portion of the Ohio River heavily influenced by industry with a large amount of barge activity. The Kanawha River empties its waters into this pool at Ohio River mile-point 265.7 and has a drainage area of $\mathbf{1 2 , 2 0 0}$ square miles. R. C. Byrd pool also receives waters from Leading Creek and Raccoon Creek with drainage areas of 151 and 684 square miles respectively. While Hydrilla sp. was not observed in site-specific vegetation surveys, evidence of Hydrilla sp. was present throughout the pool. These combined watersheds are primarily forested, but also have a considerable amount of agricultural/pastoral land.

R.C. BYRD POOL SUb-BASIN
R.C. BYRD POOL

## SURVEY SUMMARY

The pool was sampled at normal conditions during the defined index period (July-Oct). Sampling commenced two weeks after stage returned to normal conditions following months of heavy rainfall patterns. Moderate flow was observed during the two weeks of fish sampling. Notable catches include two species of concern in West Virginia, the great river species Silver Chub (Macrhybopsis storeriana; 22 individuals collected pool-wide at $\mathbf{5}$ of $\mathbf{1 5}$ sites), and Black Buffalo (Ictiobus niger; 8 individuals collected pool-wide), which was not observed in the previous two surveys of R.C. Byrd Pool. Notable macroinvertebrate collections from R.C. Byrd Pool include large numbers of invasive musseis (Dreissena polymorpha) and several tolerant species (Midges-Tribelos sp. and Dicrotendipes sp., Caddisflies- Cyrnellus fraternus, and Scuds-Gammarus sp.). Rare, intolerant species were observed in low numbers (Midges-Stempellina sp. and Ablabesmyia annulata, and Riffle Beetles- Optioservus sp.). Independent biological indices were used to apply numeric values to important components of fish and macro assemblages and to assess their relative status. The results (see above map) show that, on average, fish populations in R.C. Byrd Pool were in 'Fair' condition and macro communities were in 'Fair' condition. Overall, these results indicate that R.C. Byrd Pool supports its aquatic life use.
 Other $3.6 \%$

## SMITHLAND POOL (2019) - Healthy CONdition

Smithland Pool is 72.5 miles long, extending from J.T. Myers Locks and Dam (ORM 846.0) to Smithland Locks and Dam (ORM 918.5). The pool has a gradient drop of 0.3 feet per mile and averages 4,116 feet wide and 30 feet deep (ORSANCO 1994). The pool is bordered by Kentucky, Illinois, and Indiana. Smithland Pool lies in a portion of the Ohio River where the land cover consists primarily of deciduous forest, but also has a considerable amount of row crops and pasture lands. Smithland Pool receives water from the following tributaries: Wabash River at mile point 848.0 with a drainage area of 33,100 square miles, Saline River at mile point 867.3 with a drainage area of 1,170 square miles, and Tradewater River at mile point 873.5 with a drainage area of 1,000 square miles. The shorelines of this pool contain very little observable aquatic vegetation within littoral zones.

## Pool Surveys

The fish assessment portion of the 2019 pool surveys was successfully completed later in the year than usual due to heavy rainfall patterns during spring and summer. Fish sampling took place from Aug. $5^{\text {th }}-14^{\text {th }}$ (R.C. Byrd) and Sept. $9^{\text {th }}-12^{\text {th }}$ (Smithland). While long periods of high flow events prior to sampling were observed, stage was allowed to return to normal levels prior to electrofishing commencement. Conditions allowed for adequate sampling of fish and macroinvertebrates during the index period. The macroinvertebrate assessments for both pools were completed between September $2^{\text {nd }}$ and October $24^{\text {th }}$. R.C. Byrd Pool was assessed as meeting its aquatic lifeuse designation for both fish and macroinvertebrates (i.e. containing healthy fish and macroinvertebrate communities). Smithland Pool was assessed as meeting its aquatic life-use designation for fish, while the pool's macroinvertebrate community remained unassessed in 2019 as those data did not pass quality assurance/quality control (QA/QC) requirements. Therefore the 2019 assessment was completed using fish only.

## Assessment Comparisons

Between 2005 and 2014, all 19 Ohio River navigational pools were surveyed and assessed twice. Both cycles revealed the majority of the river to be in 'Good' condition, even though some pools changed in condition rating between surveys. The 2019 surveys continued the third cycle, which enhances our ability to
detect riverwide patterns. Some of the index and species variability observed across pools may be due in part to variations in natural distributions, instream habitat, invasive species distributions, annual variations in flow, weather conditions, and water quality.

## Present vs. Past Assessments

The focus of ORSANCO's biological assessments is to determine whether each pool is in full support, partial support, or non-support of its ALU. To aid in interpretation, we assign one of six ratings (e.g. from "Very Poor" to "Excellent") to the pools based on the relative condition of their fish communities. Shifts between years in these condition ratings may be due to variations in environmental factors other than water quality. By examining these factors (e.g. invasive species, flows, etc.) and their effects on mORFIn metrics, we attempt to provide defensible explanations for the differences in final condition ratings observed between assessments.

| Assessment Results |  |  |  |
| Avg. mORFIn Score | 31.8 | 30.8 | 26.9 |
| Fish Condition Rating | Good | Good | Fair |

R.C. Byrd pool was assessed to be in "Fair" condition in 2019. This is a condition rating lower than what was observed from the 2008 and 2013 assessments. The 15 randomly drawn sites were evenly distributed throughout the pool with 8 sites above and 7 sites below the confluence of the Kanawha River. Environmental factors such as flow, conductivity, and secchi depth were all quite comparable over the last three assessments. The primary influential factors responsible for the decline of the biological condition rating was a combination of the Avg. \% Simple Lithophil score and the Avg. \% Piscivore score. While there were several species that showed decline from previous assessments, these scores were most drastically affected by fewer observations of Sauger, Logperch, and Largemouth Bass. In review of the last three surveys of R.C. Byrd Pool (2008, 2013, 2019), the 2019 survey revealed the lowest number of observations of Gizzard Shad, Bluegill, White Bass, Spotted Bass, Flathead Catfish, and several species of redhorse. Overall scores were affected positively by the Avg. \% Invertivore score, which was likely inflated by a large catch of Channel Shiners not observed in previous assessments. While Hydrilla sp. was not observed in site specific vegetation surveys, evidence of Hydrilla sp. was present throughout pool. Further investigation is necessary to confirm that Hydrilla $s p$. is a major contributing factor to the steady decline of mORFIn scores in the upper Ohio River.

Smithland Pool

| Assessment Results |  |  |  |
| Avg. mORFIn Score | 33.6 | 31.2 | 39.2 |
| Fish Condition Rating | Good | Good | Good |

Smithland Pool was assessed to be in "Good" condition in 2019. While the condition rating has remained the same over the last three assessments, the best score was observed in 2019, less than one point shy of being upgraded to "Very Good". The 15 randomly drawn sites were distributed throughout the pool, however there were six in the upper half and nine in the lower half of the pool. Conductivity and average Secchi depth did not appear to have a significant effect on assessment outcomes. Metric performance revealed a boom in great river species, specifically Mississippi Silvery Minnows, River Shiners, Silver Chubs, and Shortnose Gar. Habitat observations in Smithland Pool were sand dominated with fine sediment being the second most abundant substrate type. Fish health appears to be improving in Smithland Pool. Avg. DELT score reflects the number of deformities, erosions, lesions, and tumors observed while identifying and measuring fish at the 15 sites throughout the pool.

Shortnose Gar (Lepisosteus platostomus)

## Macroinvertebrates

As per ORSANCO’s Biological Assessment protocol, a required minimum of 15 fish samples and/or 10 macro samples must be collected in each pool in order to derive a viable assessment. The 10 macro samples must be comprised of deep Hester-Dendy samplers and/or multihabitat kick samples. Multihabitat kick samples will only be used when deep Hester-Dendy samples are lost, unrecoverable, or otherwise disturbed, provided the multihabitat kick samples contain at least 200 individuals. Minimum sample number criteria (15 fish and 10 macro respectively) are standardized and necessary to ensure comparability between assessments.

Macroinvertebrate collections in R.C. Byrd Pool met the minimum number of samples in 2019. A total of 14 of 15 deep Hester Dendy samplers were recovered at the end of the colonization period. A multihabitat kick sample was collected at each site.

The Ohio River Macroinvertebrate Index (ORMIn) indicates that the macro community in R.C. Byrd Pool is in "fair" condition, the average ORMIn score of the 15 probabilistic sites sampled in 2019 is 22.39. Large numbers of tolerant macro species (midges-Tribelos $s p$. and Dicrotendipes sp., caddisflies-Cyrnellus fraternus) and invasive zebra mussels (Dreissena polymorpha) were observed. Notably, rare, intolerant species (midges-Stempellina sp. and Ablabesmyia annulata, and riffle beetles-Optioservus sp.) were observed in low numbers. Both fish and macro communites indicate that R.C. Byrd met its ALU designation for this assessment cycle.

Smithland Pool macroinvertebrate data did not meet QA/QC requirements, therefore a proper assessment could not be performed using the ORMIn. As such the pool was not assessed using macro data in 2019. However, based on the fish data and the results calculated using the mORFIn, the pool met its ALU designation for this assessment cycle.
