Traveltme and Dispersion Data, Including Associated Discharge and Water-Surface Elevation Data, for the Upper Ohio River, Pennsylvania, Ohio, and West Virginia, October through November 1991

By Jeffrey B. Wiley

Abstract

This report presents results of a study by the U.S. Geological Survey, in cooperation with the Ohio River Valley Water Sanitation Commission, to evaluate the traveltme and dispersion of a dye injection on the upper Ohio River. Traveltme and dispersion data, including discharge and water-surface elevation data, were collected to quantify the movement of a dye cloud in the mainstem of the upper Ohio River. The upper Ohio River originates at the confluence of the Allegheny and Monongahela Rivers, flows westward to the border of Pennsylvania, Ohio, and West Virginia, and then flows south-westward along the Ohio and West Virginia border. Knowledge of traveltme and dispersion of a soluble dye can assist river managers in mitigating the effects of an accidental spill. The potential for a spill is present because chemicals and wastes are transported by rail, pipeline, highway and barge on and near the river and tributary streams.

Daily mean discharge at 10 gaging stations and water-surface elevations for all regulated pools were collected from October 20 to November 24, 1991. Ohio River discharges were about 4,000 to 6,000 ft³/s at the Pennsylvania, Ohio, and West Virginia border during the dye study. Water-surface elevations in regulated pools indicated channel storage was fairly constant while the dye cloud was traveling through the pools.

The traveltme of peak concentration between Dashields Locks-and-Dam and Pike Island Locks-and-Dam is 609 hours. Time of passage of the dye cloud at Dashields Locks-and-Dam and Pike Island Locks-and-Dam is 80 and 129 hours, respectively.

INTRODUCTION

The Ohio River originates at the confluence of the Allegheny and Monongahela Rivers in western Pennsylvania at Pittsburgh, flows westward toward the Pennsylvania boundary with Ohio and West Virginia, and then flows south-westward along the Ohio and West Virginia boundaries (fig. 1).

The upper Ohio River provides water for municipalities and industries, and the river is used for transportation and recreation. Municipal and industrial intakes are scattered within and bordering the study area. The river is used for transporting manufacturing materials and natural resources. Recreational boating and fishing are common along the entire river.

Water quality of the upper Ohio River could be adversely affected by an accidental spill of a hazardous chemical or toxic waste. An accidental spill is possible due to transportation of chemicals and toxic waste by pipeline, rail, highway, and barge on and near the river and tributary streams. Knowledge of the movement of a spill can assist river managers in mitigation of environmental and human effects; water intakes could be closed or additional treatment could be applied, recreational uses of the river could be restricted, and regulation of streamflows could change the characteristics of the spill cloud.

On October 23, 1991, a private engineering firm injected about 240 L (590 lb) of Rhodamine 20-percent dye into the Ohio River at a constant rate of 940 mL/min from 6:00 a.m. to 10:15 a.m. to study the plume of an outfall from a sewage-treatment plant at river mile 3.2. Downstream from the plume study, a resulting dye cloud provided an opportunity to monitor traveltimes and dispersion of the mainstem of the upper Ohio River. The U.S. Geological Survey (USGS), in cooperation with the Ohio River Valley Water Sanitation Commission, undertook a data-collection program to quantify the movement of the dye cloud.

Purpose and Scope

This report presents traveltimes and dispersion data for the Ohio River from October 25 through November 23, 1991, in the study area from Dashields Locks-and-Dam to Pike Island Locks-and-Dam. Daily mean discharges are presented for 10 USGS streamflow-gaging stations and water-surface elevations are presented for all regulated pools, bordering and within the study area, during October 20 through November 24, 1991.

Description of Study Area

The upstream limit of the study area is Dashields Locks-and-Dam (fig. 1) at river mile (RM) 13.3, 50 ft downstream from the USGS streamflow-gaging station, "03086000—Ohio River at Sewickley, PA," 7.1 mi downstream from Emsworth Locks-and-Dams (RM 6.2), and 13.3 mi downstream from the confluence of the Allegheny and Monongahela Rivers; the drainage area at the upstream limit is about 19,500 mi² (Lescinsky and others, 1993, p. 101; U.S. Army Corps of Engineers, 1993, charts 195-197).

The Ohio River flows westward from Dashields Locks-and-Dam (RM 13.3) through Montgomery Locks-and-Dam (RM 31.7) to the State boundary with Ohio and West Virginia (RM 40.0), and includes the tributaries of Beaver River (RM 25.5), Raccoon Creek (RM 29.6), and Little Beaver Creek (RM 39.5) (U.S. Army Corps of Engineers, 1993, charts 190-195). The drainage area at the State boundary with Ohio and West Virginia is 23,487 mi² (Pennsylvania Department of Environmental Resources, 1989, p. 169). USGS streamflow-gaging stations 03107500—Beaver River

at Beaver Falls, PA; 03108000—Raccoon Creek at Moffatts Mill, PA; and 03109500—Little Beaver Creek near East Liverpool, OH, with drainage areas of 3,106, 178, and 496 mi², respectively, are within the drainage division of the Ohio River between Dashields Locks-and-Dam and the State boundary with Ohio and West Virginia (Lescinsky and others, 1993, p. 110-111, 113; Shindel and others, 1993, p. 48).

The Ohio River flows south from the State boundaries of Pennsylvania, Ohio, and West Virginia (RM 40.0) through New Cumberland Locks-and-Dam (RM 54.4) to Pike Island Locks-and-Dam (RM 84.2), and includes the tributaries of: Yellow Creek (RM 50.4); Cross Creek, WV (RM 71.6); Cross Creek, OH (RM 71.7); Buffalo Creek (RM 74.7); and Short Creek, OH (RM 81.4) (U.S. Army Corps of Engineers, 1993, charts 180-190). USGS streamflow-gaging stations 03110000—Yellow Creek near Hammondsburg, OH, and 03111500—Short Creek near Dillonvale, OH, with drainage areas of 147 and 123 mi², respectively, are within the drainage division of the Ohio River between the State boundaries of Pennsylvania, Ohio, and West Virginia and Pike Island Locks-and-Dam (Shindel and others, 1993, p. 49-50).

The downstream limit of the study is Pike Island Locks-and-Dam (RM 84.2), 3.3 mi upstream from the USGS streamflow-gaging station 03111534—Ohio River at Martins Ferry, OH, (RM 87.5, and about 24,700 mi² drainage area), and 42.2 mi upstream from Hannibal Locks-and-Dam (RM 126.4) (U.S. Army Corps of Engineers, 1993, charts 172-180; Ward and others, 1993, p. 130).

Acknowledgments

The author wishes to thank the U.S. Army Corps of Engineers for allowing access to river-structure properties, and providing water-surface elevations at the locks-and-dams. Thanks also to the East Liverpool Water-Treatment Plant for allowing access to properties and to the employees; Glenn Woodward, Mike Masters, Joe Miller, Jim Holmsted, and Dave Illig, for assistance in taking water samples. Mary Ann Silagy and Eric Piniero with Ohio EPA also assisted by providing samples at the East Liverpool Water-Treatment Plant. The author thanks the Allegheny County Sanitary Authority and The Chester Engineers for providing a sample of the dye injected.

Traveltme

Time-concentration curves were developed to identify traveltme and dispersion of the dye at five primary sampling sites where water samples were collected throughout the time of passage of the dye cloud (fig. 2). Traveltme of leading edge, peak concentration, and trailing edge at any primary sampling site can be determined from this graph. Reading from the x -axis of figure 2, the leading edge of the dye cloud arrived at Montgomery Locks-and-Dam at 191 hours after injection and at Pike Island Locks-and-Dam at 611 hours after injection (traveltimes of peak concentration and trailing edge can be determined similarly). Traveltme data at the five primary sampling sites shown in figure 2 are summarized in table 2. The

time required for the dye cloud to move through the New Cumberland pool can be determined from table 2 as 327 hours (time since injection of the trailing edge at New Cumberland Locks-and-Dam minus time since injection of the leading edge at Montgomery Locks-and-Dam). Figure 2 or table 2 can be used to determine the traveltme of peak concentration between Dashields Locks-and-Dam and Pike Island Locks-and-Dam as 609 hours (677–68 hours).

The leading edge of the dye cloud at Dashields Locks-and-Dam was not measured because the dye cloud had arrived at this location before field personnel were able to respond. The leading edge was estimated based on the shape of the time-concentration curve as compared with time-concentration curves for other studies.

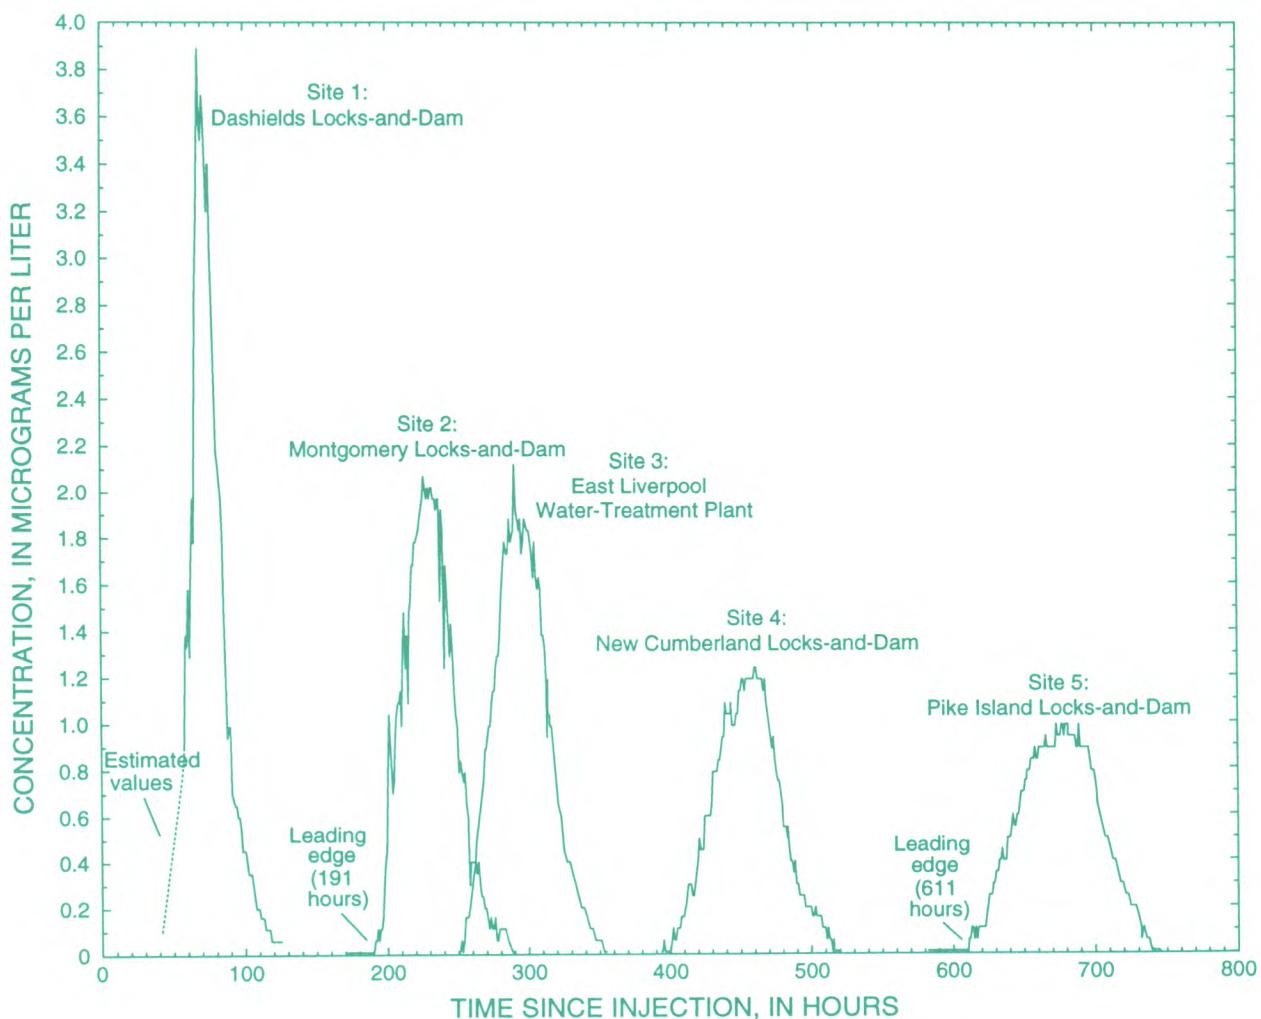

Figure 2. Time-concentration curves at the five primary sampling sites in the upper Ohio River study area.

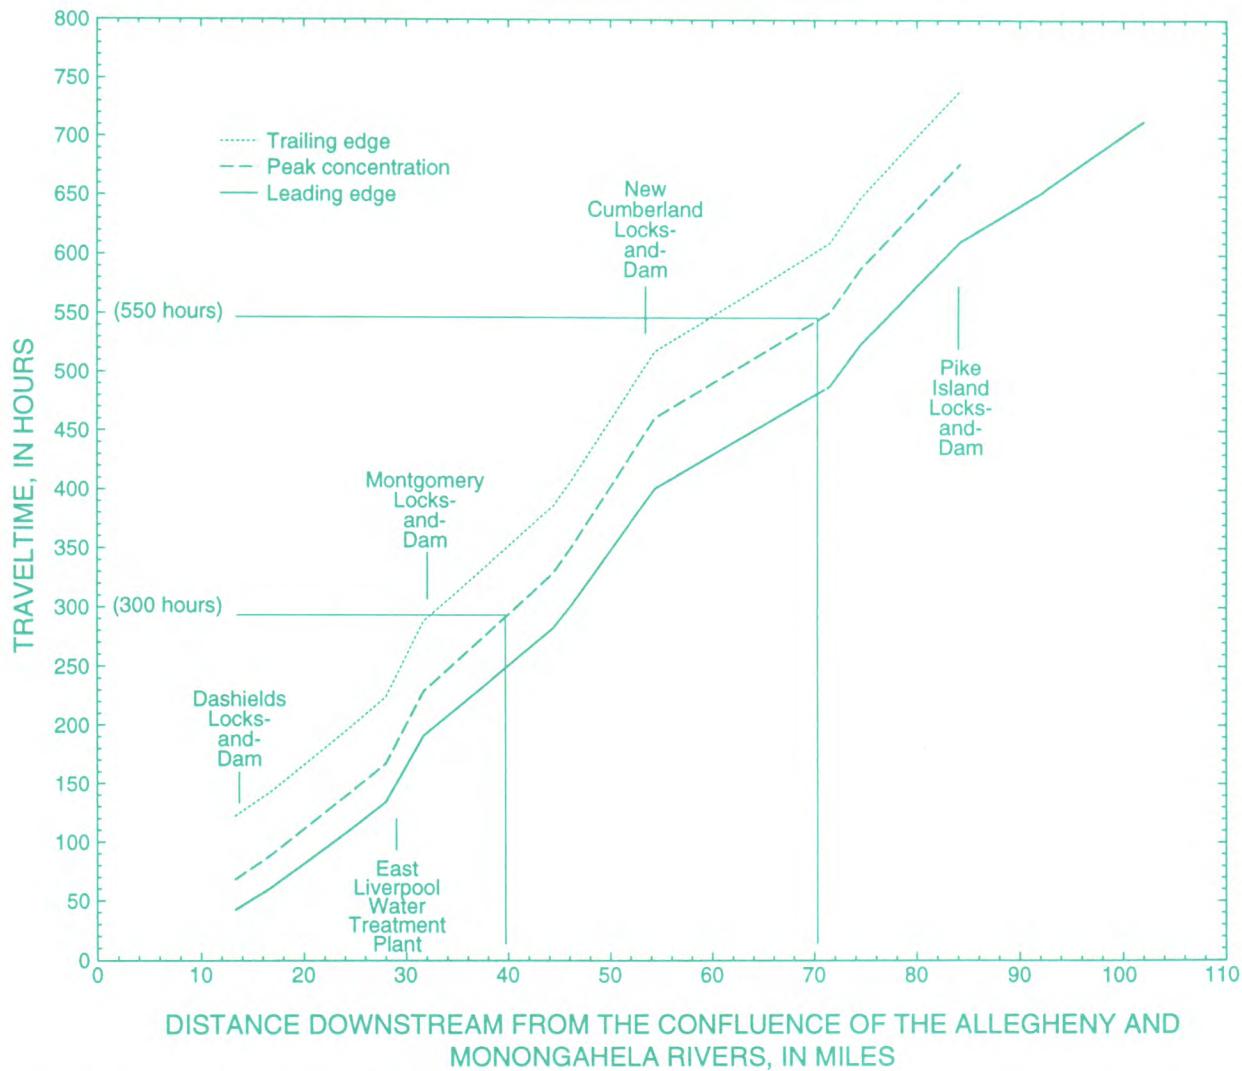

Figure 3. Traveltimes for distances downstream from the confluence of the Allegheny and Monongahela Rivers in the upper Ohio River study area.

concentration to travel from river-mile 40 (300 hours) to river-mile 70 (550 hours) is estimated from figure 3 as 250 hours, (550 – 300 hours), other traveltimes can be determined similarly.

Dispersion

Time-concentration curves (fig. 2) illustrate stream dispersion, the peak concentration decreases as time since injection increases. This is not true when comparing the peak concentration at Montgomery Locks-and Dam with the peak concentration at the East Liverpool Water-Treatment Plant. Possible explanations for this anomaly include: the peak concentration at Montgomery Locks-and Dam was not sampled because

the time interval between samples was too large to identify the sharpness of the spike in concentration; or, the sample collected at the East Liverpool Water-Treatment Plant was contaminated in the field or lab.

Time of passage of dye cloud (table 3) indicates dispersion, time of passage increases as time since injection increases. This relation also is illustrated in figure 3 by comparing traveltimes estimates between the leading edge and trailing edge (time of passage of dye cloud) at one river-mile location with traveltime estimates at another river-mile location; note, in figure 3, as river mile increases the time of passage of dye cloud increases. Table 3 or figure 3 can be used to determine the time of passage of the dye cloud at Dashields Locks-and-Dam and Pike Island Locks-and-Dam as 80 and 129 hours, respectively.

Discharge

Ohio River discharges were about 4,000 to 6,000 ft³/s at the Pennsylvania, Ohio, and West Virginia border during the dye study as estimated from U.S. Geological Survey streamflow-gaging stations: Ohio River at Sewickley, PA (03086000); Beaver River at Beaver Falls, PA (03107500); and, Raccoon Creek at Moffatts Mill (03108000). Figures 4-6 and table 5

presents daily mean discharges from October 20, 1991, through November 24, 1991, for U.S. Geological Survey streamflow-gaging stations in the study for the stations listed above and: Little Beaver Creek near East Liverpool, OH (03109500); Yellow Creek near Hammondsburg, OH (03110000); Short Creek near Dillonvale, OH (03111500); and, Ohio River at Martins Ferry, OH (03111534).

¹Lescinsky and others, 1993, pp. 101, 110, 113.²Shindel and others, 1993, pp. 48-50.³Ward and others, 1993, p. 130.

Water-Surface Elevation

Water-surface elevations at Corp of Engineers Lock-and-Dams from October 20, 1991 through November 24, 1991 indicate channel storage was fairly consistent. Figures 7-11 and table 8 show water-surface elevations at the Dashields, Montgomery, New Cumberland, Pike Island, and Hannibal pools in feet above sea level. The differences between water-surface elevations at the upstream and downstream ends of the pools remained fairly constant while the dye cloud was traveling through the pools.

An increase in channel storage was indicated near the end of the study period. Water-surface elevations increased at the upstream end of the pools relative to those at the downstream end of the pools. Traveltime of the trailing edge of the dye cloud was slightly increased by the increase in channel storage in the Pike Island pool (fig. 10); this occurrence is indicated by the arrival of the trailing edge of the dye cloud at Pike Island Locks-and-Dam after the increase in water-surface elevations downstream of the New Cumberland Locks-and-Dam. Note, this slight increase in traveltime of the trailing edge of the dye cloud probably was less significant than the decrease in traveltime resulting from the increase in stream discharge (fig. 4).

The accuracy of the absolute water-surface elevations is questionable, but the relative difference between elevations used to describe changes in channel storage is accurate. In the New Cumberland pool (fig. 9), the water-surface elevations at the upstream end of the pool (downstream elevations at Montgomery Locks-and-Dam) are less than the water-surface elevations at the downstream end of the pool (upstream elevations at New Cumberland Locks-and-Dam). Water-surface elevations also are less at the upstream end than the downstream end of the Dashields pool (fig. 7). These errors in water-surface elevations probably are due to inaccurate gage readings. Gage readings at the Locks-and-Dams used for this study were those indicated on the “Monthly Gage Report—River Stage and Precipitation Data” logs provided by the U.S. Army Corps of Engineers. The U.S. Geological Survey and the U.S. Army Corps of Engineers have acknowledged possible inaccurate gage readings (James A. Kosky, U.S. Army Corps of Engineers, oral commun., 1996).

Gage datums are presented in figures 7-11 so that possible future revisions can be accounted for by applying a correction for datum differences to the water-surface elevation data presented in table 8.
