## Introduction

Based in Cincinnati, the Ohio River Valley Water Sanitation Commission (ORSANCO) is an interstate water pollution control agency created in 1948 by an act of Congress to monitor and improve the water quality of the Ohio River. A primary goal of ORSANCO programs is to work with state agencies to develop a set of pollution control standards for the Ohio River. Monitoring programs were established to develop and refine these standards. One of these programs, the ORSANCO biological program, uses fish studies to establish biological criteria (biocriteria) for the Ohio River. These biocriteria are ultimately used to provide insight into the overall health of the river ecosystem.

In 1993, ORSANCO developed and implemented a survey design that used electrofishing methods designed for the Ohio River. After years of collecting fish population data on the Ohio River, we developed the original Ohio River Fish Index (ORFIn) which was subsequently modified (mORFIn). Each year we collect fish and environmental data from various sections of the Ohio River and use these data to calculate mORFIn scores, which are numerical representations of the relative condition of Ohio River fish communities based on a suite of measurable attributes. The resulting scores allow us to assess the biological condition of each section of the river. The information included in these assessments is further used for regulatory, restorative, and protective efforts within the Ohio River basin.

1948 - ORSANCO is created to, among other things, ensure the Ohio River is "capable of maintaining fish and other aquatic life"

How our achievements coincide with national milestones in the effort to restore our nation's water

1969 - The Cuyahoga River catches fire, fueling the movement to clean our nation's water continued nearly each year until 2005. These data comprise one of the most comprehensive river fisheries databases in existence

> 1964 - We begin monitoring aquatic bugs (macroinvertebrate) populations in the Ohio River

1975 - With the aid of several partners, we begin to sample fish tissue as a means for determining the presence or absence of certain pollutants

1987 - Fish tissue procedures are modified \& refined allowing appropriate state agencies to use the data for fish consumption advisories

1993 - We institute a semi-random sampling design allowing us a more unbiased means to assess Ohio River fish communities
2003 - The Ohio River Fish Index (ORFIn) is created

2005 - We begin routine surveys employing the ORFIn and random design, and a macroinvertebrate methods comparison study

2008 - The ORFIn is further refined \& modified creating the mORFIn

2012 - The Ohio Rive Macroinvertebrate Index (ORMIn) is created 2015 - Refined ORMIn included in annual assessments
1957 - With the aid of mulitple
partners, we begin monitoring fish populations from Ohio River lockchambers, an effort that would be

1970 - The Environmental
Protection Agency (EPA) is created

1972 - The first incarnation of the Clean Water Act, the Federal Water Pollution Control Amendments, lays the foundation for more rigorous future legislation

200
2006 - EPA expands the scope of EMAP to include "Great Rivers". We lend our expertise as trainers \& surveyors gaining valuable data for modifying the ORFIn

2008, 2013, \& 2018 - National
Rivers and Stream Assessments are conducted across the US. We participate gaining additional knowledge of the Ohio River basin

Present - We continue to work with state \& federal agencies to assess the biological integrity of Ohio River aquatic communities as directed by the Clean Water Act

## The River

The Ohio River begins at the confluence of the Monongahela and Allegheny rivers in Pittsburgh, PA and flows 981 miles in a southwesterly direction to its confluence with the Mississippi River near Cairo, IL. The Ohio has several additional large tributaries including the: Muskingum, Scioto, Kanawha, Kentucky, Green, Wabash, Cumberland and Tennessee rivers. The Ohio River itself runs through or borders six states: Illinois, Indiana, Kentucky, Ohio, Pennsylvania, and West Virginia. The river basin ( $>200,000 \mathrm{mi}^{2}$ ) covers an additional eight states: New York, Maryland, Virginia, North Carolina, Tennessee, Georgia, Alabama, and Mississippi. Nineteen high-lift locks and dams maintain a nine-foot minimum depth for commercial navigation throughout the river.

## Facts

- Average depth 24 ft , max depth exceeding 90 ft
- Average width $1 / 2 \mathrm{mi}, 1 \mathrm{mi}$ max (Louisville, KY)
- $\quad$ 344 fish species from Ohio River basin (18 exotic) $=$ $40 \%$ of known N. American species ( 800 species)
- ~178 fish species found in the Ohio River (14 exotic)
- Deciduous forests continue to dominate the basin
- Major land uses: pastures, row crops, and urban development
- Basin holds $\sim 8 \%$ of the nation ( 27 million people)
- 33 drinking water intakes provide drinking water for over 5 million people along the main stem
- 589 permitted discharges to the Ohio River
- 49 power-generating facilities on the main stem
- Coal and energy products comprise $70 \%$ of the 250 million tons of cargo carried by barges each year

## METHODS

## Site Selection

A random, probability-based survey design was used to select sampling site locations within each Ohio River navigational pool. The target areas of our surveys are both shorelines of each pool from the upstream dam to the downstream dam. The survey design provides coordinates for 15 sites (500m-long) in each of the selected pools. Biological and environmental data are then collected from these 15 sites and used to assess the biological condition of the pool.

## Fish Collection

To maintain consistency across different sampling years, fish surveys are conducted between July $1^{\text {st }}$ and October $31^{\text {st }}$ and when water levels are within two feet of "normal flat pool". Fish are collected by a non-lethal method called boat electrofishing using an 18 ft aluminum johnboat equipped with a generator and an electrofishing unit (standard equipment used by federal and state agencies). Using the electrofishing unit to regulate the output from the generator, a mild current is applied to the water with an effective range of up to 20ft. Because of our limited range, sites are fished at night along the shoreline when species are most active. This allows us to maximize the number of individuals and species captured, thus providing us with an accurate representation of the fish community at each site.

Native Ohio River fishes. Left: Members of the genus Lepomis. Bluegill, Redear Sunfish, Orangespotted Sunfish, Warmouth, Longear Sunfish. Right: Members of the genus Lepisosteus. Juvenile Shortnose Gar, Longnose Gar, Spotted Gar, Shortnose Gar.

## Collecting Macroinvertebrates

Macroinvertebrates (macros) are organisms that lack a true backbone and can be seen with the naked eye. They include aquatic insects, molluscs, arachnids, crustaceans and worms. They can range from large adult forms (e.g. crayfish), to very small larval forms of terrestrial insects (e.g. flies).

Two sampling methods are used to collect macros: Hester-Dendy (HD) samplers and multi-habitat kicks (MH). HD samplers are constructed of tempered masonite cardboard cut into 3-inch square plates and 1 -inch square spacers. Eight large plates and 12 spacers are stacked on a metal eyebolt to provide varying degrees of space for macro colonization. Five HDs are attached, in a ring, to a concrete paver. The paver is then placed on the river bottom in 10 ft of water at the downstream end of each 500 m sampling site and secured to the shore. Similar to the fish, macro sampling is restricted to a defined season within each year. HDs are deployed for six weeks, beginning September $1^{\text {st }}$ allowing adequate time for macro colonization. After the six week colonization period, HDs are retrieved and MH kick surveys are conducted.

A MH kick is performed by actively disturbing the substrate and then sweeping a net through the resulting cloud. This technique allows the sampler to collect macros without compromising the sample with large amounts of sediment. To further exclude sediments, the net heads are "D" shaped (i.e. have flat bottoms), which also eases the scraping of woody debris and boulders. Samplers disturb/scrape 10 linear meters of substrate at each 100 m interval of a site in depths 1 m or shallower. At each of these intervals, every
attempt is made to sample available habitats (e.g. sand flats, woody debris, boulders, etc.) relative to the proportion of their availability. The kicks conducted at each 100 m interval are then combined to represent the community present at the site.

Once the kicks are completed and the HDs have been retrieved, the samples are preserved. The HDs are disassembled in the field. The plates from the HDs and large debris from the MH samples are rinsed and drained through a $500 \mu \mathrm{~m}$ sieve. The macros trapped by the sieve are then transferred to a preservative jar with $70 \%$ ethanol to be identified in a laboratory. At the lab, macros are identified to species level when possible; in all other cases the highest level of taxonomic resolution is obtained. The macro information is then reviewed and imported into a database from which index scores are generated, keeping HD and MH data separate.

## Characterizing Instream Habitat

Intensive habitat surveys are conducted which include measures of woody cover, depth, prevalence of substrate types at each electrofishing site. Woody cover (e.g. submerged brush, logs, stumps) is estimated visually. More quantitative measures of depth and substrate proportions are obtained through the use of a $20^{\prime}$ copper pole. The pole is used to probe the bottom of the river to determine exact depth and the proportions of substrate types including: boulder, cobble, gravel, sand, fines, and hardpan (clay) that occur at each site.

Because different fish species prefer different habitat types, it is important to classify the instream habitat at each of our sites to better understand mORFIn score variability. Using the habitat survey data, we assign each site to one of five statistically
 derived habitat classes simply named: A, B, C, D and E. The five habitat classes represent a gradient from highly coarse Class A habitats with high amounts of cobble and gravel, to the predominantly sandy/fine substrates of habitat classes "D" and "E" which differ by water depth (see below).

## Water Quality and Hydrology

Basic measures of water quality such as water temperature, clarity, $\mathrm{pH}, \mathrm{DO}$, and conductivity are measured at each site prior to electrofishing. Water samples may also be collected at the downstream end of each 500 m zone approximately 100ft from shore to determine various water quality parameters (e.g. nutrient levels and hardness). River stage is monitored using data obtained from the U.S. Army Corps of Engineers, who also provide measures of predicted daily average flow volumes and velocities from the nearest-upstream sampling station to any particular site. These data are compiled to aid in the interpretation of the fish index results.

## A look at our five habitat classes

## Assessing Biological Condition

ORSANCO uses two biological indices to assess the condition of the Ohio River. The modified Ohio River Fish Index ( $m$ ORFIn) and the Ohio River Macroinvertebrate Index (ORMIn using HD data only) were established in 2003 and 2012, respectively. Both indices include various measures (metrics) of the fish and macro communities such as: diversity, abundance, feeding and reproductive guilds, pollution tolerance, habits, health.

\left.| 13 metrics used to generate mORFIn scores |  |
| :--- | :--- |
| Fish Metric | Definition |\(\right\left.] \begin{array}{ll}Native Species <br>

Intolerant Species\end{array} \quad $$
\begin{array}{l}\text { Number (No.) of species native to the Ohio River } \\
\text { No. of species intolerant to pollution and habitat } \\
\text { degradation }\end{array}
$$\right]\) No. of sucker species (e.g. redhorse and buffalo)

Each navigational pool is separately assessed with each index based upon the biological and environmental data collected from its 15 randomly selected sites. This involves a multi-step approach (depicted top right) that converts average metric scores ( $0-100$ ) of each individual site into final index scores (0-60), based on varying expectations of the five different habitat classes. Index scores of the 15 sites are then averaged to provide an overall score and rating for the navigational pool specific to each index.

The presence of five distinct habitat classes A, B, C, $D$, and $E$, coupled with the range of habitat preferences exhibited by individual fish and macro taxa required the translation of metric scores into relative index scores. By removing the effect of habitat, index scores can then be averaged within a pool to represent the overall condition of the biological community in question.

The averaged scores for both the mORFIn and ORMIn are then compared to a biocriterion. The $25^{\text {th }}$ percentile is the statistical threshold commonly used by regulatory agencies for establishing biocriteria. Using this threshold, our established biocriterion (i.e. a representation of healthy Ohio River fish communities) is set at an average index score of 20.0.

A pool is assessed to be in full support of its aquatic life-use (ALU) designation (i.e. possessing intact biological communities) if both the mORFIn and ORMIn scores are greater than or equal to 20.0 (i.e. a biological rating "Fair", "Good", "Very Good", or "Excellent"). A pool is in partial support of its ALU designation if only one of the indices' scores greater than or equal to 20.0, while the other index score falls within 10.0-19.9 (i.e. a "Poor" rating). Any pool in which both indices score below a 20.0, or in which at least one index scores below 10.0 (i.e. a "Very Poor" rating), would be considered in non-support of its ALU designation.

For more detailed information pertaining to our programs including survey design, field methods, past \& present assessment results, or biological data contact one of our staff or visit: www.orsanco.org/biological-programs

## 2022 POOL SURVEY RESULTS

The results of the 2022 biological surveys are detailed in the following pages (relative pool locations shown below). Included are brief descriptions of the land use \& hydrology, site level mORFIn \& ORMIn ratings, summaries of notible catches \& instream habitat, and the overall biological condition of each pool.

## Belleville Pool (2022) - Healthy Condition:

 Dam (ORM 203.9). The pool has a gradient drop of 0.5 feet per mile and averages 1,327 feet wide and 24 feet deep (ORSANCO 1994). The pool is bordered by West Virginia and Ohio and lies in a portion of the Ohio River moderately influ enced by industry and barge activity. The largest cities along the pool are Marietta, OH (the oldest city in the state) and Parkersburg, WV. The Belleville pool has three large tributaries, the Muskingum and Hocking Rivers in Ohio and the Little Kanawha River in West Virginia. Combined, these tributaries drain an area of over 10,000 square miles. The pool has multiple islands scattered throughout its reach, providing a variety of habitats for aquatic species. The watershed is primarily forested ( $55.72 \%$ ), and is also comprised of pasture lands (18.28\%) and row crops (11.87\%).

## SURVEY SUMMARY

3
Electrofishing sampling took place over one week in early July at the begining of the index period (July-Oct). Sampling conditions were favorable marked by low flows and high Secchi readings; however water temperatures were the highest on record (avg=24.9; max=32.6 degrees C). Three species considered to be "irruptive species" comprised $75.9 \%$ of the total catch: Gizzard Shad (Dorosoma cepedianum, $\mathrm{n}=\mathbf{1 , 0 3 4}$ ), Channel Shiner (Notropis wickliffi, $\mathrm{n}=\mathbf{3 1 8}$ ), and Emerald Shiner (Notropis atherinoides, $\mathrm{n}=\mathbf{2 7 8}$ ). Notable catches included one Ohio species of concern (River Redhorse, Moxostoma carinatum, $\mathrm{n}=1$ ) and one individual that typically inhabits small-medium rivers was captured in between the Muskingum and Little Kanawha Rivers at RMI 176.4 (Silverjaw Minnow, Notropis buccatus). Of the 2022 macroinvertebrate assessments, the highest species diversity was observed in the Belleville Pool, with 118 unique taxa collected. Notable macroinvertebrate collections from Belleville Pool include Alderfles (Sialis sp.; $\mathrm{n}=2$ ), eight different species of Dragonflies and Damselflies (Order: Odonata), and 29 different EPT taxa including Winter Stoneflies (Taeniopteryx sp.; $\mathrm{n}=16$ ) which are sprawler/clinger detritivores that are generally intolerant to pollution, though some species are adapted to large polluted rivers. Independent biological indices were used to apply numeric values to important components of fish and macroinvertebrate assemblages and assess their relative status. The results (see above map) show that, on average, fish populations in Belleville Pool were in 'Fair' condition and macroinvertebrate populations were in 'Good' condition.

## Olmsted Pool (2022) - <br> Healthy Condition

The Olmsted Pool is 46.3 miles long, extending from Smithland Locks and Dam (ORM 918.5) to Olmsted Locks and Dam (ORM 964.8). The pool has a gradient drop of 0.3 feet per mile and averages 3,500 feet wide and 20 feet deep. The pool flows adjacent to Kentucky and Illinois and lies in a portion of the Ohio River with a large amount of barge activity. It has two major tributaries: the Cumberland and Tennessee rivers with drainage areas of 17,920 and 40,910 square miles, respectively. The pool's watershed is primarily forested ( $57.9 \%$ ) but also has a considerable amount of pasture lands (19.3\%) and row crops (5.5\%).

## Pool Surveys

The fish assessment portion of the 2022 pool surveys was successfully completed during the normal sampling timeframe. Fish sampling took place from July $11^{\text {th }}-13^{\text {th }}$ (Belleville), July $25^{\text {th }}-27^{\text {th }}$ and August $22^{\text {nd }}-25^{\text {th }}$ (Olmsted), and August $19^{\text {th }}-21^{\text {st }}$ (Open Water). Electrofishing surveys took place under normal stage and flow conditions. Conditions allowed for adequate sampling of fish and macroinvertebrates during the respective index periods. The macroinvertebrate sampling for all four pools was completed between August $29^{\text {th }}$ - Oct. $26^{\text {th }}$. Belleville, and Olmsted pools were assessed as meeting their aquatic life-use designations for both fish and macroinvertebrates (i.e. containing healthy fish and macroinvertebrate communities). Open Water remained unassessed as this unimpounded region of the river contains unique hydrology and habitats for which the biological indices are not currently calibrated.

## Assessment Comparisons

Between 2005 and 2022, all 19 Ohio River navigational pools were surveyed and assessed three times. All three cycles revealed the majority of the river to be in 'Good' condition, even though some pools changed in condition rating between surveys. The 2022 surveys concluded the third cycle, which enhances our ability to detect riverwide patterns. Some of the index and species variability observed across pools may be due in part to variations in natural distributions, instream habitat, invasive species distributions, and annual variations in flow, weather, and water quality.

## Present vs. Past Assessments

The focus of ORSANCO's biological assessments is to determine whether each pool is in full support, partial support or non support of its ALU. To aid in interpretation, we assign one of six ratings (e.g. from "Very Poor" to "Excellent") to the pools based on the relative condition of their fish communities. Shifts between years in these condition ratings may be due to variations in environmental factors other than water quality. By examining these factors (e.g. invasive species, flows, etc.) and their effects on mORFIn metrics, we attempt to provide defensible explanations for the differences in final condition ratings observed between assessments.

A Sauger (Sander canadensis) collected from J.T. Myers Pool.

## CONCLUSIONS

| Belleville Pool |  |  |  |
| :---: | :---: | :---: | :---: |
| (Fish = FA/R, Macros = GOOD) |  |  |  |

| Silver Chub | 32 | 1 | 0 |
| Assessment Result |  |  |  |
| Avg. mORFIn Score | 34.6 | 24.5 | 20.9 |
| Fish Condition Rating | Good | Fair | Fair |

Belleville Pool was assessed to be in "Fair" condition in 2022, exhibiting decreasing mORFIn score trends over the past three assessments. The 15 randomly drawn sites were distributed evenly throughout the 42.2 mile long pool, with three sites above the Muskinghum River and seven sites downstream of the Little Kanawha River. The three highest scoring sites were in the upstream segment of the pool clustered around the mouth of the Muskingum River, while the lowest performing sites were in the lower pool just upstream of the Belleville lock and dam. Water temperatures were the highest observed on record, accompanied by low flows. While the impact on assessment results is not entirely clear, we speculate that since these conditions drive fishes into deeper, colder water, it may have contributed to the depressed CPUE metric as our sampling gear is limited by water depth. The observed fish community declined in both abundance and species richness over the past three assessments, which is directly reflected in the Avg Species Score, and subsequently reflected in various other metrics shown above. Another factor possibly contributing to lower metric scores is the observed shift in substrate composition, providing less suitable habitat for fishes that are indicative of healthy aquatic ecosystems. Course substrates (boulder, cobble, \& gravel) declined from an average of $41 \%$ to $29 \%$ between 2009 and 2022. Fine sediments increased by $26.3 \%$, rendering a more homogenous habitat that can host fewer native
species, and often species that are pollution tolerant. Pollution intolerant species have consistenly declined, comprising $27.8 \%, 23.1 \%$, and $17.0 \%$ of the sampled fish community, respectively. The aforementioned trend was mostly driven by Smallmouth Redhorse and Channel Shiners, two species that fall into other imperiled metric calculations as well. The Simple Lithophil Score exhibited a steady decline between the three assessments, as they require course substrates to spawn and many of these species happen to be pollution intolerant. The relative abundance of simple lithophil species decreased from $29.2 \%, 25.0 \%$, to $21.1 \%$ respectively, and they comprised $13.9 \%, 14.0 \%$, and $4.0 \%$ of the total catch, respectively.

Olmsted Pool
(Fish = FAIR, Macros = VERY GOOD)

| Assessment Result |  |  |  |
| Avg. mORFIn Score | 30.2 | 36.8 | 24.7 |
| Fish Condition Rating | Good | Good | Fair |

Olmsted Pool was assessed to be in "Fair" condition in 2022, which is a lower condition rating than the previous two assessments. The 15 randomly drawn sites were fairly evenly distributed throughout the 46.3 mile long pool. Environmental factors such as flow, conductivity, and Sechhi depth did not appear to have a significant effect on assessment results. Water temperature was the highest observed on record peaking at 36.6 degrees Celcius. The average temperature was 33 degrees Celcius, which is equal to the maximum recorded temperature of 2009 and surpassing the maximum temperature of 2014 by roughly 4 degrees. Primary factors responsible for the
decline of the biological condition rating over the three assessments was the overall reduction in species richness reflected in the Average Species Score (15 fewer species observed), Average Centrarchidae Score, and the Average Percent Simple Lithophil Score. The abundance and diversity of the Centrarchidae family decreased from $14.9 \%$ to $1.6 \%$ of the fish community, with a reduction from 10 to 4 species observed. The Average Percent Lithophil score was most drastically affected by fewer occurrances of Sauger and Silver Chub, and the diversity of this breeding guild has declined from 9, to 8, to 6 species, respectively. Historically and presently, the substrate of Olmsted pool has been dominated by sand and fines, meaning the community composition changes are likely attributed to other factors. The most plausible explanation for these declines is the substantial increase in water temperature. Higher temperatures drive fishes in to deeper water in search of reprieve from the heat, which affects our ability to capture them with electrofishing gear that is limited by water depth.

An invasive Silver Carp (Hypopthalmichthys molitrix) collected from Olmsted Pool.

## Open Water

(Unnassessed)
This is the most downstream stretch of the Ohio River, it is unimpounded from Olmsted lock and Dam to the confluence of the Mississippi River. The habitat in this stretch of river and the corresponding fish and macroinvertebrate communities are vastly different from the rest of the Ohio River. The Indices of Biotic Integrity (IBI) that are used to evaluate the pools of the Ohio River are not effective here. Until more data are collected and assessments tools are refined using said data, this stretch of river cannot be assessed using the current approach that is applied throughout the rest of the river. ORSANCO biologists are collecting additional data from this stretch of the river to develop a protocol that would eventually allow for an assessment of this unique area of the basin.

## Macroinvertebrates

As per ORSANCO's Biological Assessment protocol, a minimum of 15 fish samples and/or 10 macro samples are required to be collected in each pool in order to derive a viable assessment. The ten macro samples must be comprised of deep Hester-Dendy samples (HDD) or multihabitat kick samples (MH). Multihabitat kick samples will only be used when deep Hester-Dendy samples are lost, unrecoverable, or disturbed, provided the multihabitat kick samples contain at least 200 individuals. Minimum sample number criteria ( 15 fish and 10 macro respectively) are standardized and necessary to ensure comparability between assessments.

An Adult Burrowing Mayfly (Hexagenia limbata).

## Belleville Pool

Macroinvertebrate collections in the Belleville Pool met the minimum number of samples in 2022. 14 HDD samplers were recovered at the end of the colonization period. The Ohio River Macroinvertebrate Index (ORMIn) indicates that the macroinvertebrate community in Belleville Pool is in "Good" condition, with the average ORMIn score of 36.61.

ORSANCO biologists processing macroinvertebrate samples
The most abundant macroinvertebrates present in the Belleville Pool were chironomids, specifically from the genus Dicrotenipes. Aside from chironomids, the second most abundant taxa in the collections from 2022 were from a genus named Hydrobiidae, more commonly known as mud snails. Zebra Mussels and Scuds made up a large percentage of catches as well. There was also a high abundance of moderately tolerant mayflies-- Heptageniidae commonly known as Flathead Mayflies (Stenacron sp.).

Dragonhunter Clubtail Dragonfly Naiad (Hagenius brevistylus) collected from Olmsted Pool.

The greatest species diversity was observed in the Belleville Pool, with the presence of 118 unique taxa, rendering the highest score for the Number of Taxa metric.

Seasonal biologists retrieve a Hester Dendy sampler at the end of the colonization period.

## Olmsted Pool

Thirteen HDDs were retrieved from the Olmsted Pool. The 2022 assessment score of 43.37 classifies the Olmsted Pool to be in "Fair" condition for macroinvertebrates.

The most notable macroinvertebrate collection from the Olmsted Pool is the Dragonhunter Clubtail Dragonfly (Hagenius brevistylus). This species has been collected 4 times in the history of ORSANCO's monitoring programs. Zebra Mussels have been observed colonizing on the wide abdomen of this species of dragonfly. This large predatory species is a sprawler and is often imperiled in areas with high abundance of Zebra Mussels. Other notable collections from the Olmsted Pool included high abundance of midges and 18 different EPT taxa including a high percentage of tolerant Trumpetnet/Tubemaking Caddisflies (Cyrnellus fraternus) and Common Netspinner Caddisflies (Hydropsyche orris). Zebra Mussels (Dreissena polymorpha), scuds (Gammarus fasciatus), and tolerant mayflies (Hexagenia limbata) were also observed in large numbers.

## CONCLUSIONS

Our assessments would not be possible without the guidance of our committee and hard work of our Seasonal Biologists. For information on seasonal employment opportunities available to recent graduates, contact Rob Tewes (rtewes@orsanco.org).

Look for our mobile 2,200 gallon educational aquarium displays at festivals and events along the Ohio River filled with fishes from local areas.

To request a
"Life Below the Waterline" display at your event, contact Sarah Segars (ssegars@orsanco.org)
for pricing and scheduling
